

31/a

ed, as shown on the progress maps accompanying each report of the Director.

This is being published in sheets of convenient size, 2 by 20 inches. The four-sided area of land represented in an atlas sheet is bounded by parallels and meridians called a *quadrangle*. The quadrangles mapped cover

latitude by 1° of longitude, 30' of latitude by 30' of longitude, 15' of latitude by 15' of longitude, or smaller areas, of the area mapped depending on the scale used. Scales are employed. The smallest scale, that used

(quadrangles covering 1°, is 1:250,000, or very nearly 4 inches—that is, 4 linear miles on the ground is represented by 1 linear inch on the map. This scale is used

of the desert regions and some other parts of the far west. For the greater part of the country, which is mapped in quadrangles covering 30', a larger scale, 1:125,000, or

miles to an inch, is employed. A still larger scale, 1:62,500, or about a mile to an inch, is used for quadrangles

of 15', the unit selected for mapping thickly settled or agriculturally important areas. A fourth scale, 1:31,250, or one

to an inch, is employed for maps that are to be used in connection with irrigation or drainage, and a few maps of districts are published on still larger scales.

Geographic survey of Alaska has been in progress since 1899, and nearly 30 per cent of its entire area has now been mapped. One-third of the area mapped, or 10 per cent of the

Y., has been covered only by reconnaissance work, the rest of which have been mapped on a scale of about 10 miles to an inch. The maps of nearly all the remaining two-thirds of surveyed area have been published on a scale of 100,000, or about 4 miles to an inch. These maps are large, presenting 2° of latitude by 4° of longitude. A few

The shale below the 10" shaly ls bed contains many *Stroptelasma* (cup corals), also *R. spiniferoides*, and *S. pennatus* and *T. erimatus*. The 10" bed also has the *Stroptelasma* but is very shaly and poorly defined. However the *Stroptelasma* will serve to orient.

Lichas
1 1/2 miles SE of E.B

The *Lichas* consists of a lower layer of hard grey ls of about ~~12~~ 15" thickness, then 1 1/2' of shale adorned with ls and crinoid fragments, then 5" hard grey ls succeeded by shale.

In the 1 1/2' layer of sh. *D. laticosta*, *Lichas*, *Stroptelasma*, *R. spiniferoides*, *S. pennatus*, and *T. erimatus* were found.

In the 5" ls. bed were seen *R. rana*.

The lowest layer bears the most crinoidal material there.

1978

East Bethany

At the East Bridge over the Tachumna west of E. Bethany station, Decatur Co., Ga. The bottom of the river is about 101-102' above sea level. The composition of the river bottom is mostly sand and gravel. The banks along the side of the R.R. Decatur river at this bridge are the "Encinal". The exposure is a fairly good one for collecting a variety of fossils. The lower part of the section is a weathered shale, probably a fossiliferous shale. Fossils are abundant in the shale.

Five miles E from the R.R. crossing the Tachumna river is a small stream at about 975' above sea level. Along the banks and bed of the stream is about 1' of soft bluish shale. Above this is a layer of limestone in two layers. The lower layer is hard bluish grey ls. with many small fossils. The upper layer is 1-2' thick of fine grey, crinoidal ls. These two layers dip strongly to the west. Many of the fossils are collected and probably from the rock which weathers to a light yellow brown.

About 3' below the heavy massive layer of limestone there is weathered shale without any fossils in it. Upstream about 250 yards from the crossing of the stream and the bridge the

Shale with Le. Larrea and
Ostracods is in full force, this is
at approximately the location the RR track
it was not possible to measure
the complete thickness of the Centerville

from the top of the S. side of the
Centerville to the S. base of the S. side

Shale containing ground is located at
RR curve. Shale is in stream about
100 yds. west of the curve.

440 paces west of Centerville RR bridge
to S. side, in about 1/2 mi. of distance
the bed is 20' above the RR track.

400 paces from RR bridge. Shale is
in fault. From the S. side of fault
is on west side about 1/2 mi. above the tracks.
Upthrown side is east about 1/2
mi. above the tracks. The dip is about
1°. The Phacelostoma bed makes a shallow
trough in the west side at 460 paces
20' above the tracks, at 440 16' above the
tracks, the dip is reversed at the fault
being 18' above the tracks.

The ~~Phacelostoma~~ fault plane dips E.
The Phacelostoma bed dips approximately
1° W about 35 paces west of the fault.
332 paces from bridge it is dipping 2 1/2°
by compass. It is 6' above the tracks
at 332 having dipped 6' in 68 paces or
204' per mile.

From 332 paces to 132 paces from the
bridge no rock is exposed. At 132

Fauna in the Monticelli —

A. speciosus
P. hana

A. andreae
A. granulosa

Elliot Creek was visited in an effort to work
 out the zones in the upper part of the
 Moscovian, but they could not be very much
 satisfactorily determined. These are Brown
 Brook. The Kaskaskia shale was clear enough
 but only one small lot of Ambocoelia
 preserved. The search for this fossil. The
 Window, shale seems to be very thin and a
 layer of limestone, especially like the
 Stopletona and seems not above than
 5 or 6 feet below the base of the Seneca.
 The base of the Moscovian has the same
 fossiliferous layers of limestone with a
 fauna that is of Languan from the
 Old Fichon, with which the Moscovian
 appears to agree. The *A. granulosa* beds
 were not seen either at Elliot Creek or
 Window Creek or Brown Brook. Perhaps
 northward these beds have ~~been~~
 thinned out. Certainly they are in full
 force on Cayuga Creek.

The Ambocoelia zone is close to the top of Tichenor in the exposures at Bull's Bridge and Cogenovia Creek but at Laramie it is way above it suggesting northward overlap on my Roubidoux shale.

Pictures today

2 of purple Laramie Creek

1 Roubidoux shale Elliott Creek

1 Tichenor Elliott Creek

Trilobite bed Murder Creek

Montic 2 Murder Creek

One of the concretions in the band just under the Genundewah ls. contained a *Leiorhynchus*. *S. tellus* was not seen in these upper shales.

Where the Moscovite shales are exposed in the banks they fall into small chips, but in the stream beds they preserve a sort of concretionary structure.

The Genundewah ls. 500 yards from top of Tichenor in stream bed!

Section on the shore between Clover Banks and Avery's ravine

Above the *Strophalosia* bed were

3' of fissile shales soft and crumbling easily.

3' Ludlowville

6" *Strophalosia* bed

In the clay and broken fragments 1/3' above

SK-

12' 10"

Strophalosia bed 2 spec.

of *P. stylipora* were found and *S. pinnatus*. These were not in place but still are not far from their origin

Note on Avery's Creek.

According to Grabau the *Pleurodictyum* beds are exposed on Avery's Creek but at their level is now a pond. This section must have been dammed in both places quite recently, thus covering up the *Pleurodictyum* beds. The upper Ludlowville bed were not carefully examined as they were scattered up the stream & their exact position was difficult to determine.

Cliff at Torrey

16" hard ls.

17" Grey ~~shale~~ shaly limestone

Black fissile shale

Black shale abundant in ls. limestone

7" Black fissile shale

Water level

1000

The fauna about 35' below the contact with the Hennessee and above a stratum of ls. about 35' below the contact contains *S. andersoni*, *Styrolithus*, *R. conradi*, *A. reticularis*,

6 steps from top of ls. band
1/4 in. thick.

7' above the 6" calcareous shale comes a band of shale that bears many corals, *Heliphyllum*, *Systiphyllum*, *Endophyllum* etc., *Thamnia*, *Forchites*. It is a shale mixed with ls.

20' 5" from the top of the six inch band of ls. is another about 4" thick.

At 1442 paces in stream bed the rock is hard and calcareous & have *Chaetetes* sp. and *O. undulata*. On these are softer shales. These hard beds also have huge *Phacops rana*, *H. sekoyi*, *S. pennatus*, *Homonas*.

At 1490 paces *Chaetetes* is very abundant forming small reefs of branching forms. Here also were seen *S. conradi*, *Cystodictya*, *S. pennatus*, *Conarotocchia*, *Platyceras*, *Chaetetes*, *A. spinulosa*, *P. rana*, *C. coronatus*, *S. bellus*, *Terebratulids*, *Favosites*, *D. aculeatus*,

Section at 950 paces.

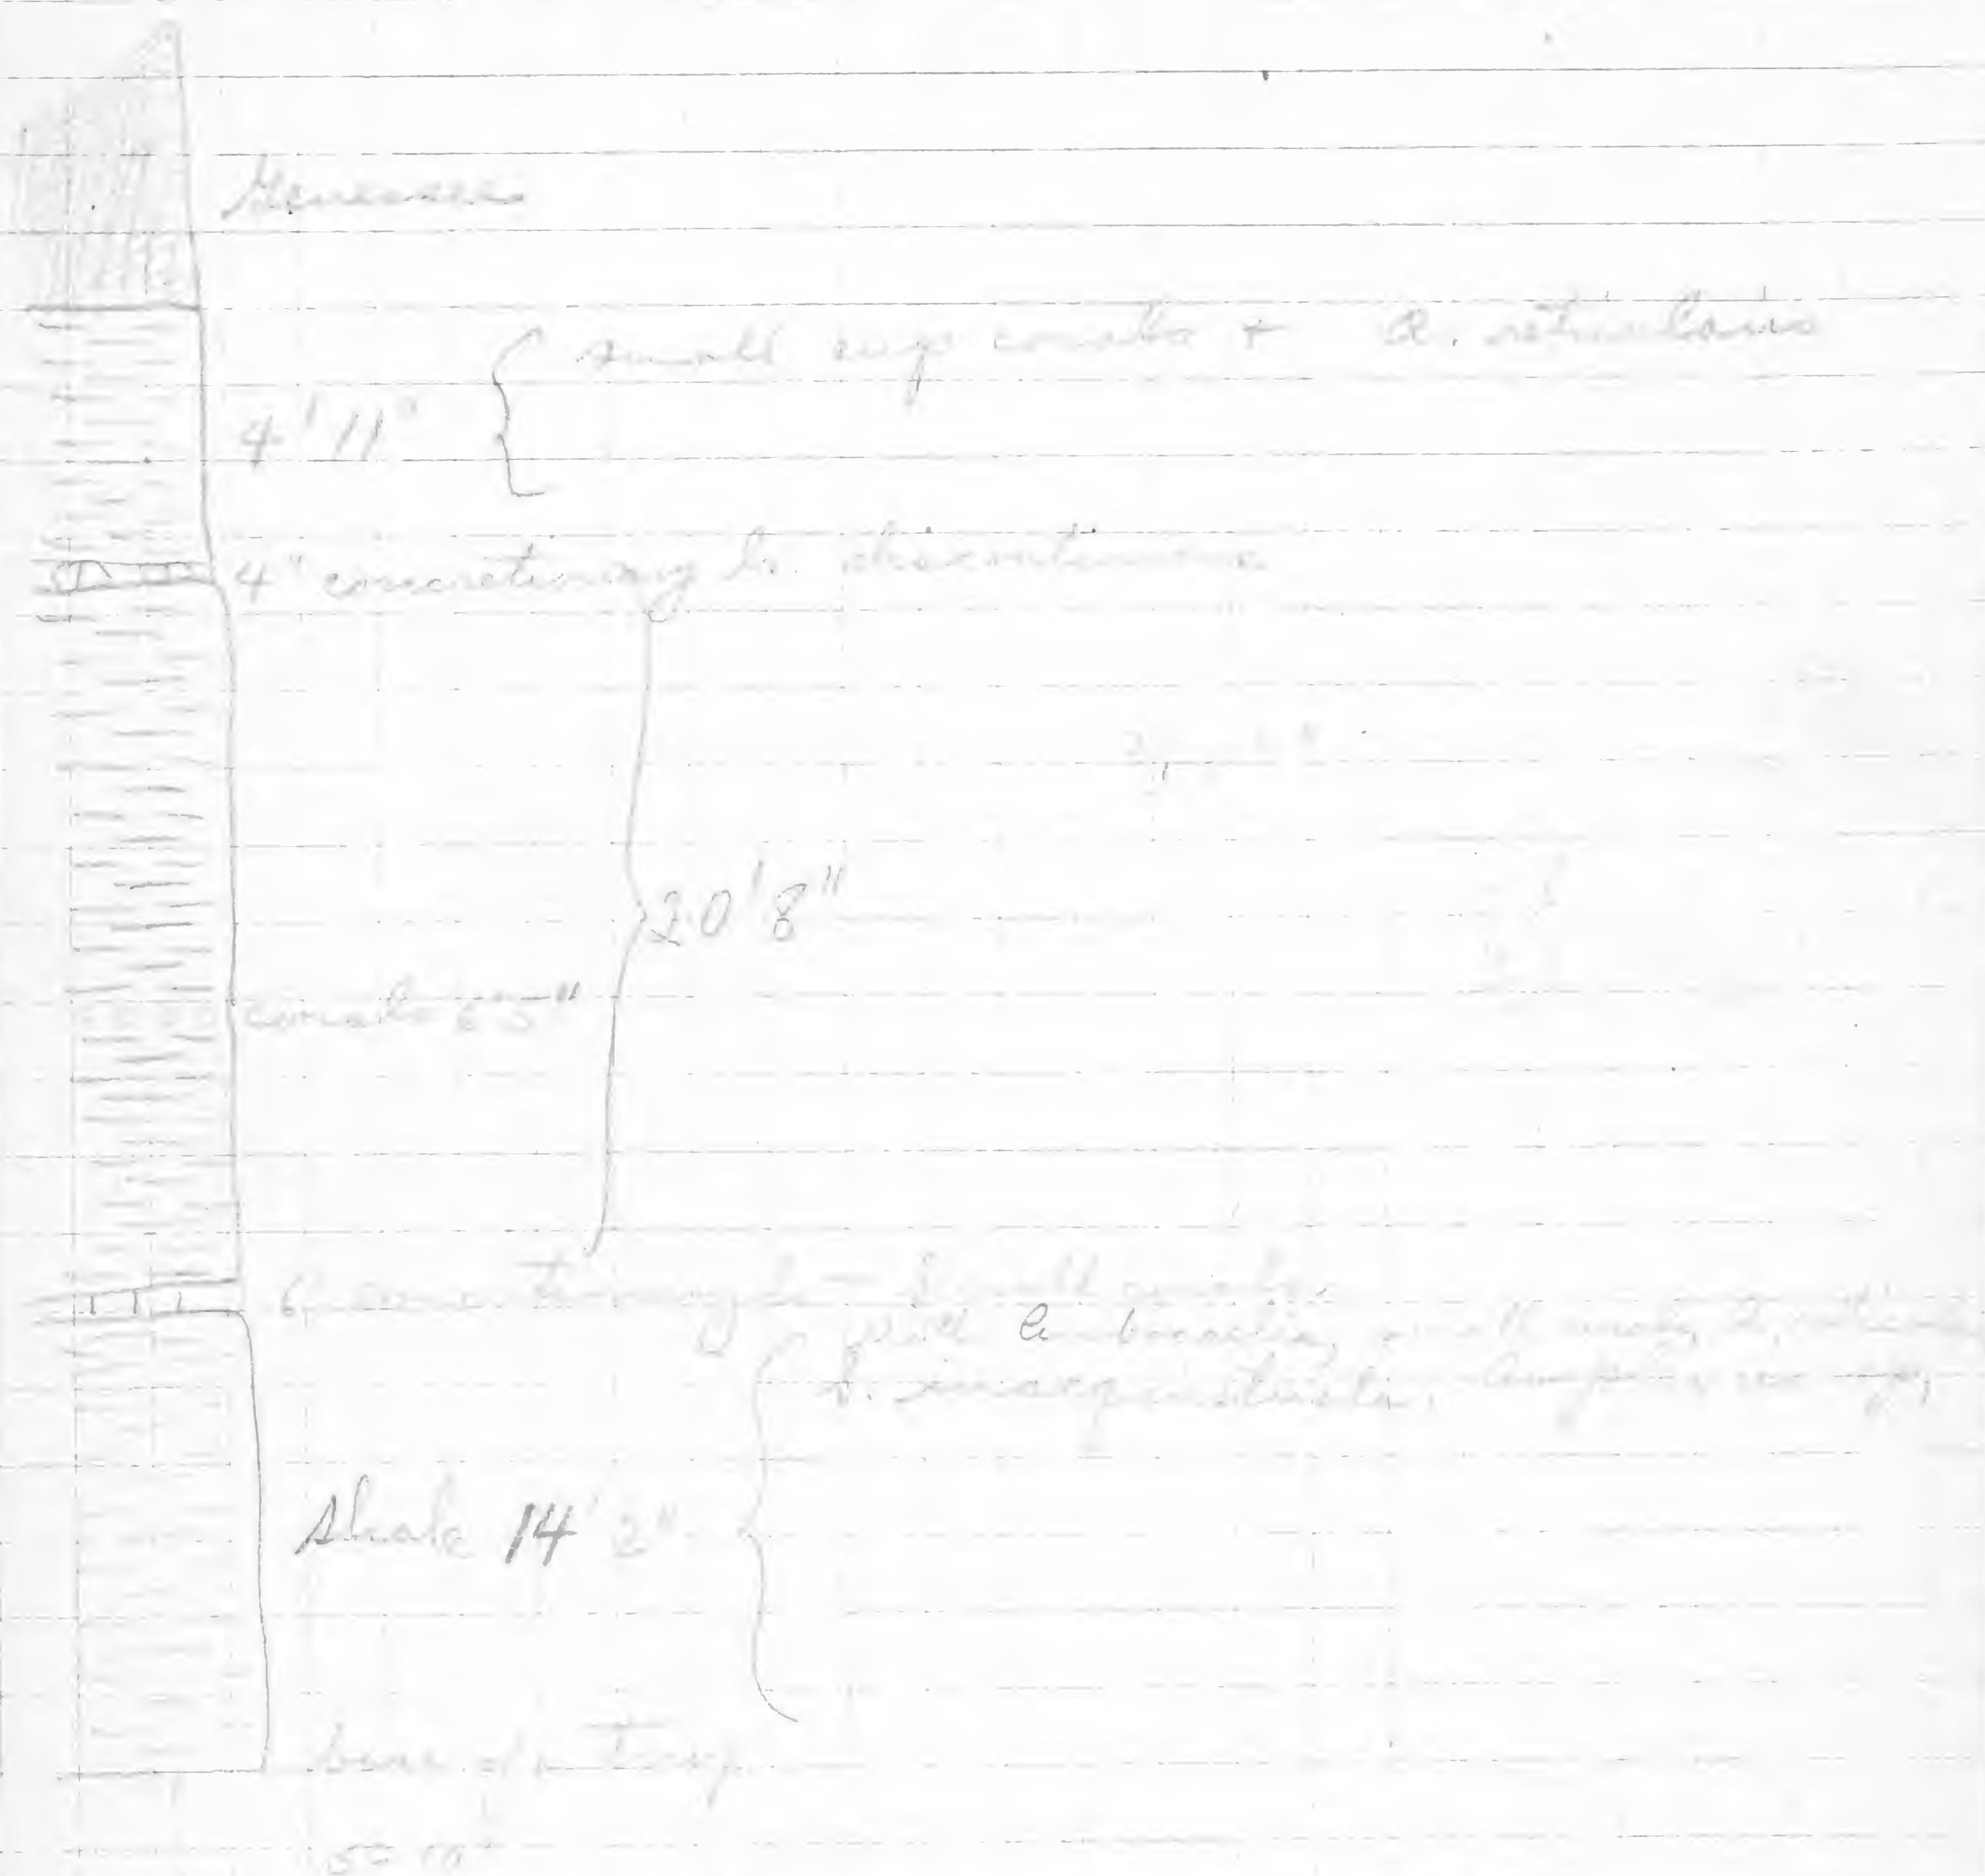

The fossils at 1490 paces are in general localized to the lower part of the section. The horizon is right at the intersection of the two streams at B.

147 paces upstream from intersection B was found *S. schuchardi*.

832 paces upstream from B the following fauna was found: *P. rostrata*, *S. pinnatus*, *Ambricocella* sp., *C. scutellus*?

Section 555 paces S of road

55 10'

Section 555

Section 555 paces south

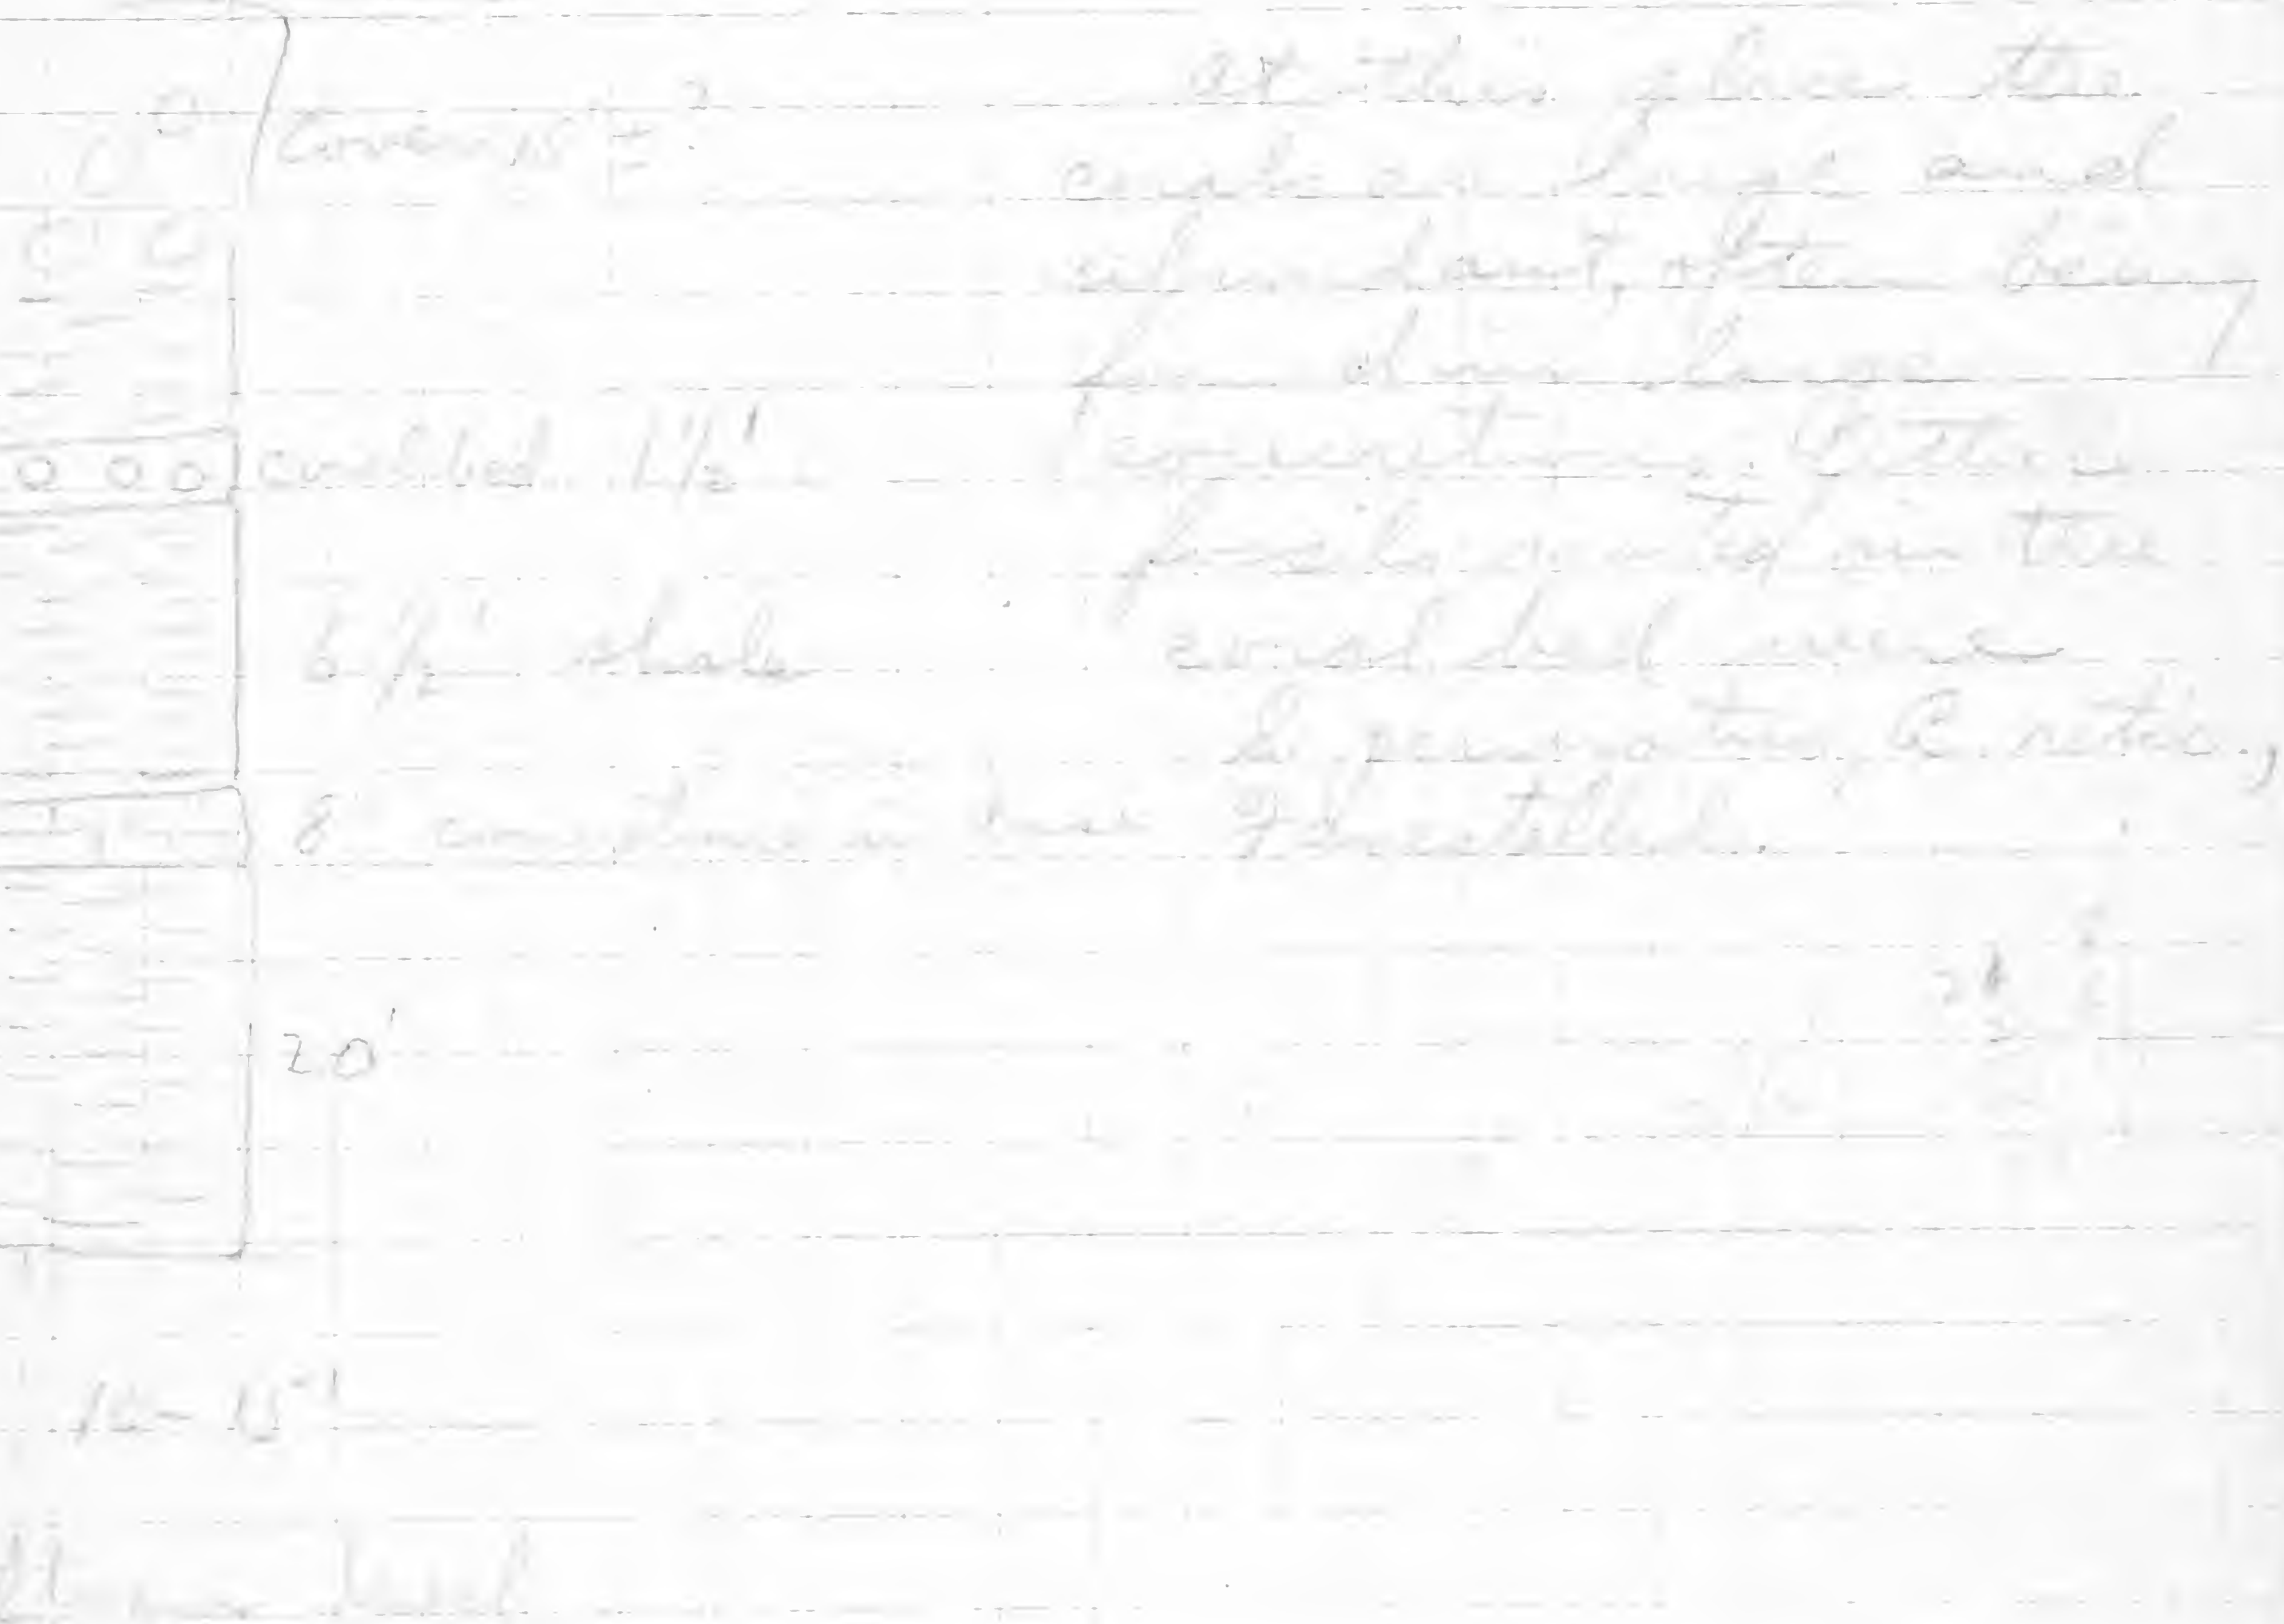

In the last 5' 5" of shale on the 6' band of ls. are found corals (small) large graptolites

About 6' 5" above the ls. (6') comes a band of corals with *Heliophyllum*, *Cyrtophyllum*, and small *Favosites*

At 20' 8" above the lower band of ls. comes a concretionary band of ls. that is here quite discontinuous. In the 20' interval small cup corals are prominent. In the upper 4' 11" of shale pyrite concretions occur

It seems a rule that pyrite concretions are most abundant in the upper 10' feet (arbitrary) or so of the section. The discrepancy between this section and that 700 paces to the north is probably due to cover.

Section 675 paces south of road

At 450 paces ~~at~~ south of road had in section on page 1 of July 28th 5. notes the coral bed occurs at 24' 2" above the top of the 6" calcareous bed with *E. micranatus*. The concretionary ls here below the corals is not prominent as it is exposed only in a joint face.

The coral bed and limestone below are well exposed at Fall Brook.

Section 250 paces north of road

Between 3rd & 4th steps were
found small corals & A. etc.
Just below the 6th step the coral
bed was met and it is about 2 1/2'
thick. It has large flat, oval
coral, in section with coral also.
Favosites, P. spinosa, Bryozoa, A. spiriferoides.

Pgite

shale 30"

5" corals

Shaded area shows probable position of bed at the 4th
step. It is seen.

11'

coral bed 2 1/2'

shale

30' 30"
32' 6"

The ls. bands cannot
be distinguished here as
they are too disintegrated.
They are probably not
good horizon markers.
A small, thin pyrite
lens (1/2" thick) was
found here.

About 24' up occurs
a hard calcareous band.

5' 5"
stream level

At 453 paces in the debris a
Planoliticus was found. It was one and
the others in the debris do not look
like the Ludlowville Planoliticus.

The beds above at the stream
intersection (upper) with the Charlotte, Homestead
to belong to beds considerably lower
than the Jossil horizon.

July 28th

Little Bands Creek

4.5 p.m. south of shot road, or about

1000 ft. south of intersection of stream
between a shale above the
6" band and the shale
(probably not far from the
most fossiliferous shale)
(*Th. applanatus*, *P. planus*), *A. a.*
reticulatus and *P. a.*

Greenish to light tan
no pyrite seen

Above the 9" band (upper)

4' 8"

concretionary to 4"

of concretionary to 4" were
found only a few small
corals and *A. reticulatus*.

The lower 2' 5" is hard
crystalline and contains
Orthis, *C. muscipatus*,
Chonetes sp., *C. scutellatus*
and *C. applanatus*.

crystalline
6' 11" } 2' 11" 8"

shale
6"

about
1" thick
fossiliferous

16' 3"

shale 6' 5"
thin bed

5.5 p.m. south of shot
road in woods is a large
exposure of Worcester shales.
Here the shales below the
6" band are well shown.
The bottom of this exposure
is fully 5-10' above
stream level. It is best
exposed from the base of
the exposure as the woods
prevent any such exposure
from the stream level.

450

454a

~~450~~

July 27.

Just outside (west) of pavilion the contact of the Senessee & Moscow occurs about on the 980' contour. Here occurs a course of concretions about 20" below the contact. *R. reticulatus* occurs below the concretions, *R. cyclops*, *S. pennatus* above, but the shales above the concretions are not very fossiliferous.

1927

July 21

Murder Creek

In stream opposite schoolhouse
(Loc. 1) a series of ls. and shales bearing
abundant fossils. The stream bed is
a 4" layer of hard limestone with
S. denissa *R. fimbriata* (horizon?)

*S. pinnata**Helicospira*, etc.

Below this ls. is the thin shales,
ls. and shales. These have *Lichas*,
S. pinnata, *Camerotheca*, *Camerotheca*,
S. conseria, *Trilobites*, *Bygonia*, etc. This
probably belongs to the lowest ls. at

Blossom. The next bed above

4" ls. is a bed of shales

bearing the following fossils

Favosites large*P. conseria**C. brachyoma* with tubes*Camerotheca* sp.*Cyrtina* *harvillensis**A. reticulata* (small)*A. denissa**Cyrtina*?3" ls. with *S. pinnata*

Scale 7"

4" with *S. denissa*

?

Below follows a thin shales
bearing *S. pinnata* fossils. The
fossils are small and few & can be found
in the shales. The shale is about 7"

Then there is a 3" layer of ls. with
S. pinnata

At A a little more than 1/2 mile
south of the schoolhouse on the
east bank of the creek are 5-9' of
shales just covered with *Trilobites*
Trilobites, *S. pinnata*, *S. pinnata*, etc.
foundly *Trilobites* and *S. pinnata*
rare *Trilobites* and *S. pinnata*

Ludlowville Shale

Tier

20-30' shale - water between top + bottom

6' P. stylipora + corals

6' P. stylipora + corals

6' P. stylipora + corals

Shale should be about
90' to the 1st bridge
upstream from the
schoolhouse

(p. 45) ?

4' 2'

Shale 1' with *L. quadrata* + *L. line*

42' 40' ?

Shale 1' ? water top 10' to 20' consistently

Centerville ls. 4' ?

Dips about 2' on 100 yds

When figuring this section from
the historical point be stated that
the Phacelina bed and that between
the T and the M. subalata bed. It will
be noted that about 20-40' interval
between the Phacelina bed and the
Creek bottom at Elmer. The
Centerville could therefore best have
been far off.

The Ludlowville has about
as at Coopersville about 10'

+ other ostracoda

The shale is dark blue gray on the surface but dark grey with a faint suggestion of brown in section. On a sectioned surface there goes on ready effervescence with acid.

In top of this shale occurs a band of ls. about 1" thick. Below the ls. fossils are most numerous but of the same kind. *H. l. ligura* is not common, + *C. setigera* + *C. lepidus*, *S. truncata*?, *Ostracoda* and *trilobites*, also *M. punctata*.

This hard 4" band of limestone forms a bench across the stream. The fauna of this band is not very prolific but the following were observed.

P. laevis

A small *Strophomena*

N. triquetra

Portion of a *Crinoid* like animal? Fish

The shales on this ls. are like those below lithologically and faunally. Fossils noted were,

Ostracoda,

P. fragilis

C. setigera

S. pinnatus

C. lepidus

S. fissurella

Leptæna and shell fragments of it

Amboecia (sp.)

In a core taken the same fossils were noted and in addition *S. truncata*,

P. spinulicosta

Schuchertella cf. parvica.

The *Phanerotoma* bed is a puzzler now if this is it here (and it must be) it is not the equivalent of the centerfield ls. but is about 30' above it.

At the base and below the concretionary layer *S. pinnatus* becomes very abundant. Also here are found *P. rana* and *S. pinnatus* in mass.

Small elongate forms that come
from the shale. B. lada was
taken from a concretion
bed with.

The *Pleurodictum* bed crosses the stream
336 paces downstream from the first
bridge. 60 paces upstream the concretionary
bed before noted crosses the stream.
Fossils noted in the shale and concretions
are: - *P. rana* c

| | |
|------------------------------|---|
| <i>I. carinatus</i> - r | <i>S. minutum</i> v12 |
| <i>A. umbonata</i> (var?) cc | <i>Orthis</i> sp. r |
| <i>S. truncata</i> c | <i>Pleurodictum</i> - highly sculpted |
| <i>B. lada</i> - r | <i>P. spinulicosta</i> c |
| <i>Lox. hamulterius</i> r | <i>S. punctatus</i> c |
| <i>C. boottii</i> - r | <i>Paleosolenia</i> <i>truncatula</i> v12 |
| <i>M. corbularius</i> r | <i>S. punctatus</i> c |

The assemblage suggests an equivalent
to the *Strophomena* bed. The concretions
here are rounded or elongate
masses flattened vertically. Some of them
are fully 10' long. In them fossils are
very abundant, particularly *A. boottii* as in
Strophomena.

In the next six ft of shale the following
fossils were seen: -

A. spiniferoides
A. angulata
P. stylopoda

In the lowest 2' of shale *P. stylopoda*
was found with *S. punctatus*, *S. minutum*,
Strophomena, etc. 4" above the
Pleurodictum occurs here a coral
reef of *Phylloporus*, *Trachypora*, *Chama*,
Favosites (argus) and a branching *A. l.*
whose species name is subequitum
(cannot think of genus) *P. punctatus*
P. stylopoda

In the shales above the reef
A. spiniferoides, *S. pennatus*, *R. penelope*
 are seen. *Plummitum* and *I. comatus*
 were found in the reef.

In the shales above the reef at 179 paces
 were found *S. granulatus*

I. comatus
A. spiniferoides
R. fimbriata
Bygonia
R. penelope
S. pennatus
S. comatus

In the foot wall of shale below
 the ls. the following fauna was
 recognized at 250 paces upstream

P. rowensis n.
Streptasma cord. c *P. punctilifera*
S. pennatus c
A. spiniferoides c
R. penelope n.
I. minutum
Bygonia many - sub-shaped, narrow, with
C. lenticularis
P. rowensis
Ceratopora
A. subulata

This shale is lithologically like
 that below. It represents the shale
 below the *Beaumont* at the second
 down at Group.

The 4" band of ls. splits readily into
 slabs as it is probably well weathered. This
 stone has the following fauna:-

| | |
|---------------------------|--------------------------|
| <i>I. minutum</i> n. | <i>P. rowensis</i> n. |
| <i>C. lenticularis</i> n. | <i>S. pennatus c</i> |
| <i>B. lenticularis c</i> | <i>M. pygmaea n</i> |
| <i>P. tenuistriata n</i> | <i>S. fissurella n</i> |
| <i>M. subulata n</i> | <i>Schuchertella sp.</i> |

*M. oblongatus**M. Truqueti**A. umbonata**Palaemonites concentrica*

This has the largest no. of *Palaemonites* as far noted, except for the layer in Sholes Creek. which is the same

Following this is a 10" of soft grey shales with

S. pennatus cc.*Hyophron**P. rana**C. laticosta**C. lepidus**C. spiniferoides**P. truncatus**P. punctiliferus**A. umbonata**C. laticosta**Schistotheca* cf. *arctostictus*

Following this shale are 5" more of ls. with

*S. fissuralia**C. truncatus* ?*S. murina**M. oblongatus**M. subulata* cc*P. rana**B. leda* (common)*C. bellistincta**S. pennatus**Orthoceras* sp*Palaemonites concentrica**C. truncatus*

This is probably the *M. subulata* bed of Grubbs.

Each of these 2 beds of ls. crumbles readily under the hammer but they are resistant enough to form ledges in the stream. At 290 paces up stream the 4" layer is seen.

At 325 paces soft shales with

*S. pennatus**C. laticosta**C. lepidus**C. scitulus*

Between 325 + 535 paces there are no exposures but at 535 paces a small exposure of soft shale bedded

Each of
abundance of
L. lancea and L. pinnatus with
T. subulatus and a large Spirifer, spec.
? and a large macropter.

At 500 paces from the water you
the following fauna -

| | |
|--------------------|-----------------|
| A. spiniferoides c | P. rana |
| L. lancea cc | St. d. |
| L. pinnatus cc | Th. lineata |
| Th. umbonata cc | C. bothri |
| C. aculeus c | Pteropoda sp. |
| L. perplanus cc | P. pinnatifidus |
| Strophomena cc | P. ovata |

At 650 paces the thickness of
the strata is about 15' above the water
level. The strata below this
at 570 paces is about 20' below the
T. level also are numerous
concretions.

At 720 paces are seen

| | |
|------------------|-------------|
| L. umbonata cc | |
| L. pinnatus | Th. lineata |
| P. rana | are present |
| L. perplanus | |
| A. spiniferoides | |

From 800-825 paces the shales in
the bank are not very fossiliferous.
A. spiniferoides being almost abundant.
The vertical shales are exposed
in the bank and where they are
adjacent to the soil and for a
half foot below they have been
attained to a light olive color.

At 870' there is a 5' 6" section with
 mainly blue gray shales for 5'. The
 last foot is weathered to olive shale.
 At 4' vertically to the column, *A. spiniferoides*
Schuchertella and *S. pennata* were
 observed. In the weathered blue
 shale fossils are abundant. This
 horizon is not far below the
 Tichenor. Here are

Strophomena cc

R. cyclos

R. banyanensis

Favosites

S. pennata

Schuchertella acts.

E. perplana

S. truncata?

A. vitreolana

P. nana

M. conseriosa

Cystites bany.

R. fructuosa

P. flabellum

Cystites bany.

S. truncata?

The rock is exposed from 870'-1100'
 where the Tichenor is met.

Tichenor ls.

The first layer is about 6" thick of
 nodular irregular crystalline ls. with many
 corals, both cup and
 compound. One 3' across
 had measures fully 1 1/2'

across,
 4' 6" in this lower
 layer and

The

July 22
Murder Ck

At 241 paces above the highway bridge at Limer are blue-grey shales, soft and crumbly in the creek-bed. These contain large calcareous concretions. The following fossils were discovered:

Cystites
S. pinnatus
Archilepterus sp.
N. corollaria
Brachygonia sp.
T. cuneatus

At 258 paces *Pleurodictyon* with very large cups.

At 320 paces a band of concretionally limestone crosses the stream. This contains:

T. cuneatus
S. pinnatus
P. brachygonia
S. pinnatus
C. bulbata
Lingula sp.

C. bulbata
This stone is only about 3" thick. This stone is hard and forms a ledge in the stream, it has a very irregular fracture under the hammer.

This is succeeded by a soft grey shale containing:

C. coronatus
Lingula sp.
T. cuneatus
Chonetes

This shale continues to 500 paces where it is almost a mud. It is so soft and wet. The exposure is only about 2 ft vertical. The stone breaks into large slabs of irregular size, in sections it is white and in air it is grey.

surfaces. When it is dry it
crumbles. The fauna here is the
most striking I have so far
met. The predominant form is
I. carinatus, very numerous & very
large; next in abundance is *C.*
carinatus, then *I. pinnatus*. Other
forms are

I. gordini?

M. concentrica

C. bellistriata

Cyrtolites dentellus

Platystrophia cf. *conjugata*

C. bellistriata

C. setigera

Lygella sp.

Cammarotoechia sp.

Præva - large

C. brithi

Pteronotus

At 5 1/2' there are also
Enaliothis & *Platystrophia* of size
as above and in addition

Orthopora carinata

Cammarotoechia in shale and in the

dark shale small flat black

Cammarotoechia are common like those

at Carlisle railroad cut.

1st floor - blue grey banded shale
with *Præva* and small black
concretions. I saw here there are no
stratig. for 1st floor where a
series of rounded concretions are
exposed on the stream bed.

At 4 1/2' floor and up the banded
beds are blue grey banded
with *Præva* concretions. *Platystrophia*
is abundant. *Pteronotus* on each one

Half feet are occupied by blue grey shale, then a thin line of concretions. Then a layer of bluish siliceous rock, chertaceous in texture about one ft. Below this was $1\frac{1}{2}$ ' shale. On top are about 2' shale.

2' shale
 1' bl. shale & concretionary
 1' shale
 1' stream

 this exposure is
 C. reticularis
 C. punctata
 W. bairdi
 C. punctata

About 15 paces upstream from the Diamond highway bridge are found soft shales. The beds that are 1' thick (about 1' vertically) are to be found about 1' (covered about 50 paces in creek) is a hard band of concretionary ls. This has the following fossils:

P. ovata
 S. punctata
 C. bairdi
 I. submarginata
 C. reticularis (small + with thin ribs)
 C. ovata
 R. penelope
 Cup corals
 R. finbriata

Some of the ls. lenses in this hard shaly ls. are almost completely made up of C. reticularis.

in the shale below the l. the following fossils were observed
Schuchertella parvula (large)

C. baxteri

C. baxteri

A. large Stenodonta

Thalysidites

A. apicifera

B. furcata

B. sinuata

A. reticulata

B. planatensis

About 200 yds north of the railroad crossing in the stream bed about 100 yds north of the dam the contact of the Moscow & Genesee is at above stream level. This contact must cross the stream just above the dam, at about the railroad crossing. A thin layer of limestone here showed the former presence of a pyrite lens.

Above the concretionary bed are 6'-7' of soft shales, with a sparse fauna. Fossils noted were:

C. levis

C. letipora

C. sinuata

Spindleria

Spindleria sp.

However - noted in other section of Moscow also.

Small cap coral.

This layer of ls. is about 1' thick
and very nodular due to small
concretions in the lower layers
which are shaly. At the top of the
upper the fragments of ls. Many of
these ls. fragments contain small
concretions of white. Pyrite
concretions are abundant in the
shale below this ls.

Remains of *Yucca* are reported
here.

July 25

Lancaster

Kingman River with upper bed now covered by pond. This is upstream from Coyne St. Foundry St. is now called Holland Ave.

Warden Creek

Bluestone bed 5' thick is 365 paces downstream from first bridge above the lower school.

63 paces upstream from the bridge is a coralline layer 6' thick abounding in small *Archaeodonta* & like the ones seen in Cayuga. There is also present a *Strophomena* bed. *Alpheia* & *Strophomena* are seen in it.

Lower *Strophomena* bed is 340 paces upstream from bridge and is 6' above *Strophomena* bed.

[Faint, illegible handwritten text, likely bleed-through from the reverse side of the page.]

311c

The conventional signs used to represent these are shown and explained below. Variations appear on maps, and additional features are represented on maps.

Water features are represented in blue, the smaller streams by single blue lines and the larger streams, the sea by blue water lining or blue tint. Inter-
ms—those whose beds are dry for a large part of the year are shown by lines of blue dots and dashes.

Relief is shown by contour lines in brown, which on some maps are complemented by shading showing the effect of light from the northwest across the area represented, for the purpose of giving the appearance of relief and thus aiding in the interpretation of the contour lines. A contour line represents an imaginary line on the ground (a contour) every part of which is at the same altitude above sea level. Such a line may be shown at any altitude, but in practice only the contour lines at regular intervals of altitude are shown. The sea level itself is a contour, the datum or zero of altitude. The 20-foot contour would be the line where the sea should rise 20 feet. Contour lines show the shape of the hills, mountains, and valleys, as well as their successive contour lines that are far apart on the one hand indicate a gentle slope; lines that are close together indicate a steep slope; and lines that run together indicate a cliff. The manner in which contour lines express altitude, form, and relief is shown in the figure below.

of the State of New Mexico, are shown in the accompanying map. They are to be used in the publication of maps on a scale of 1 inch = nearly 2 miles), with a contour interval of 25 to 50 feet.

The topographic survey of Alaska has been in progress since 1897, and only 27 per cent of its area has now been mapped.

403d

PHIC MAP OF THE UNITED STATES

The contours of course they surround hills. Those sinks are usually indicated sice, on the inside of the erval, or the vertical dis- contour and the next, is each map. This interval he character of the area

their descriptions, as well as the descriptions and geodetic coordinates of triangulation stations, are published in the annual reports and bulletins of the Survey. The publications pertaining to specified localities may be had on application.

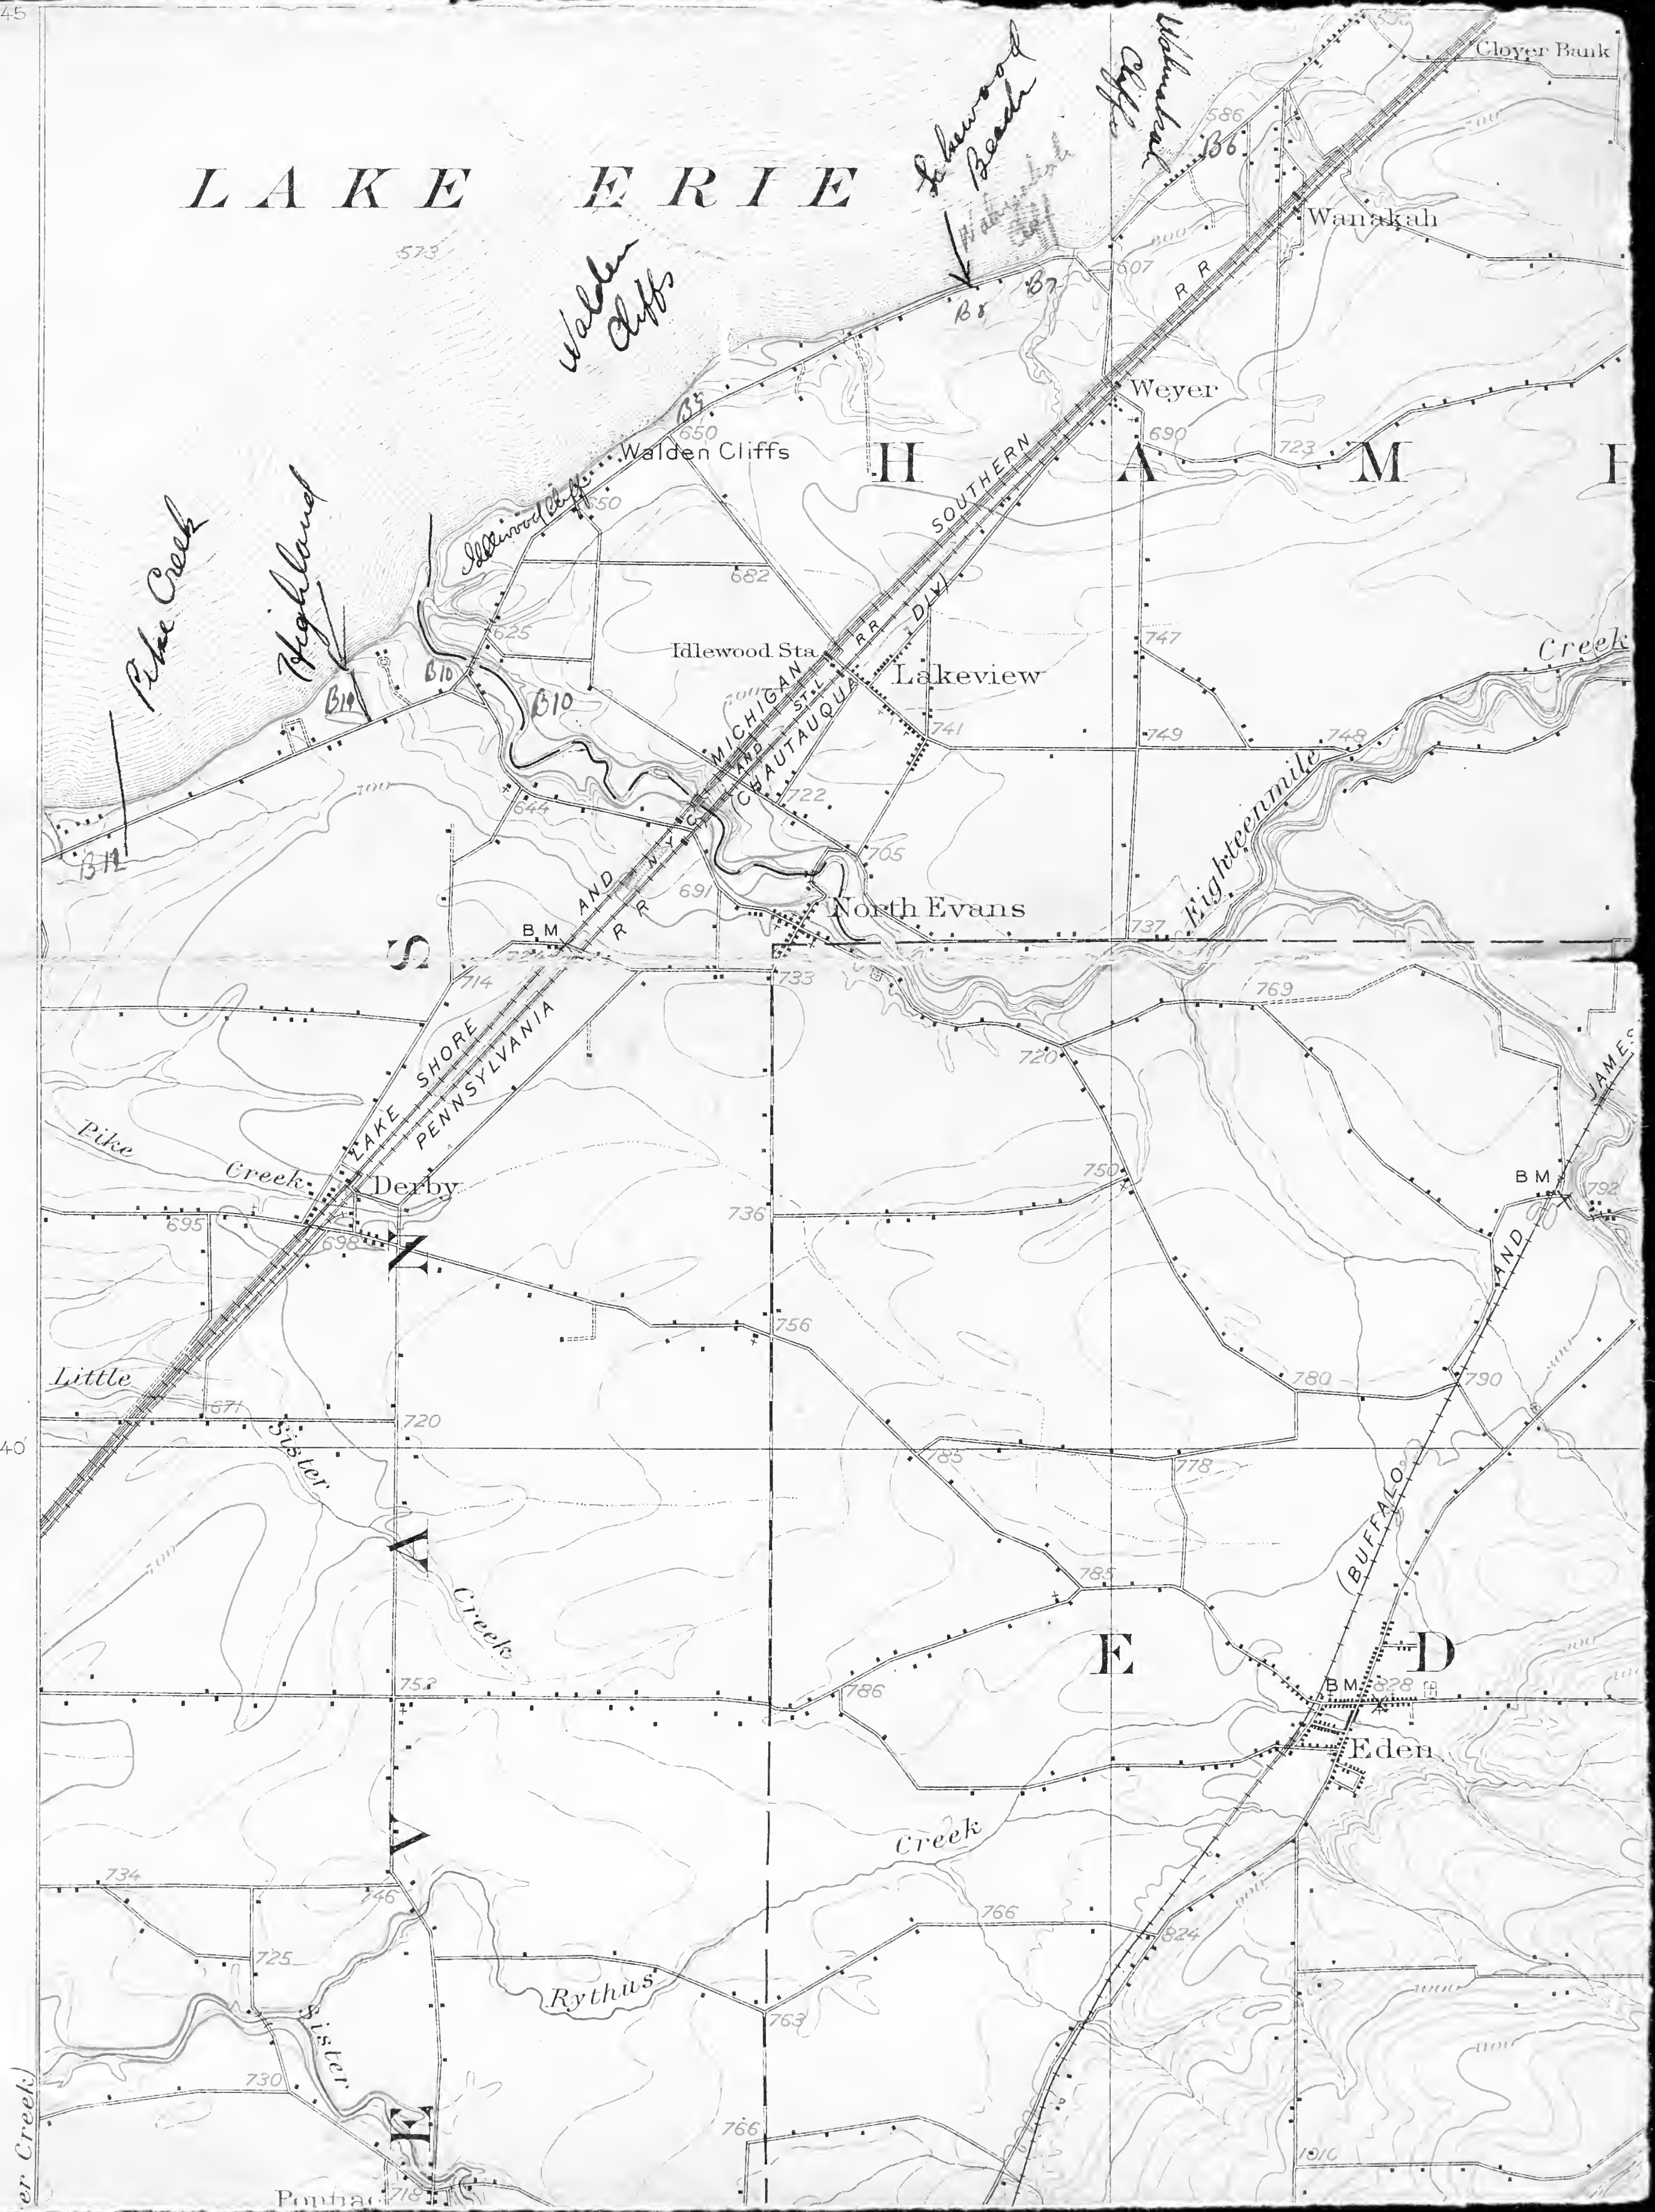

The works of man are shown in *black*, in which color all lettering also is printed. Boundaries, such as State, county, city, land-grant, reservation, etc., are shown by broken lines of different kinds and weights. Cities are indicated by black blocks, representing the built-up portions, and country houses by small black squares. Roads are shown by fine double lines (full for the better roads, dotted for the inferior ones), trails by single dotted lines, and railroads by full black lines with cross lines. Other cultural features are represented by conventions which are easily understood.

The sheets composing the topographic atlas are designated by the name of a principal town or of some prominent natural feature within the district, and the names of adjoining published sheets are printed on the margins. The sheets are sold at five cents each when fewer than 100 copies are purchased, but when they are ordered in lots of 100 or more copies, whether of the same sheet or of different sheets, the price is three cents each.

The topographic map is the base on which the facts of geology and the mineral resources of a quadrangle are represented. The topographic and geologic maps of a quadrangle are finally bound together, accompanied by a description of the district, to form a folio of the Geologic Atlas of the United States. The folios are sold at twenty-five cents each, except such as are unusually comprehensive, which are priced accordingly.

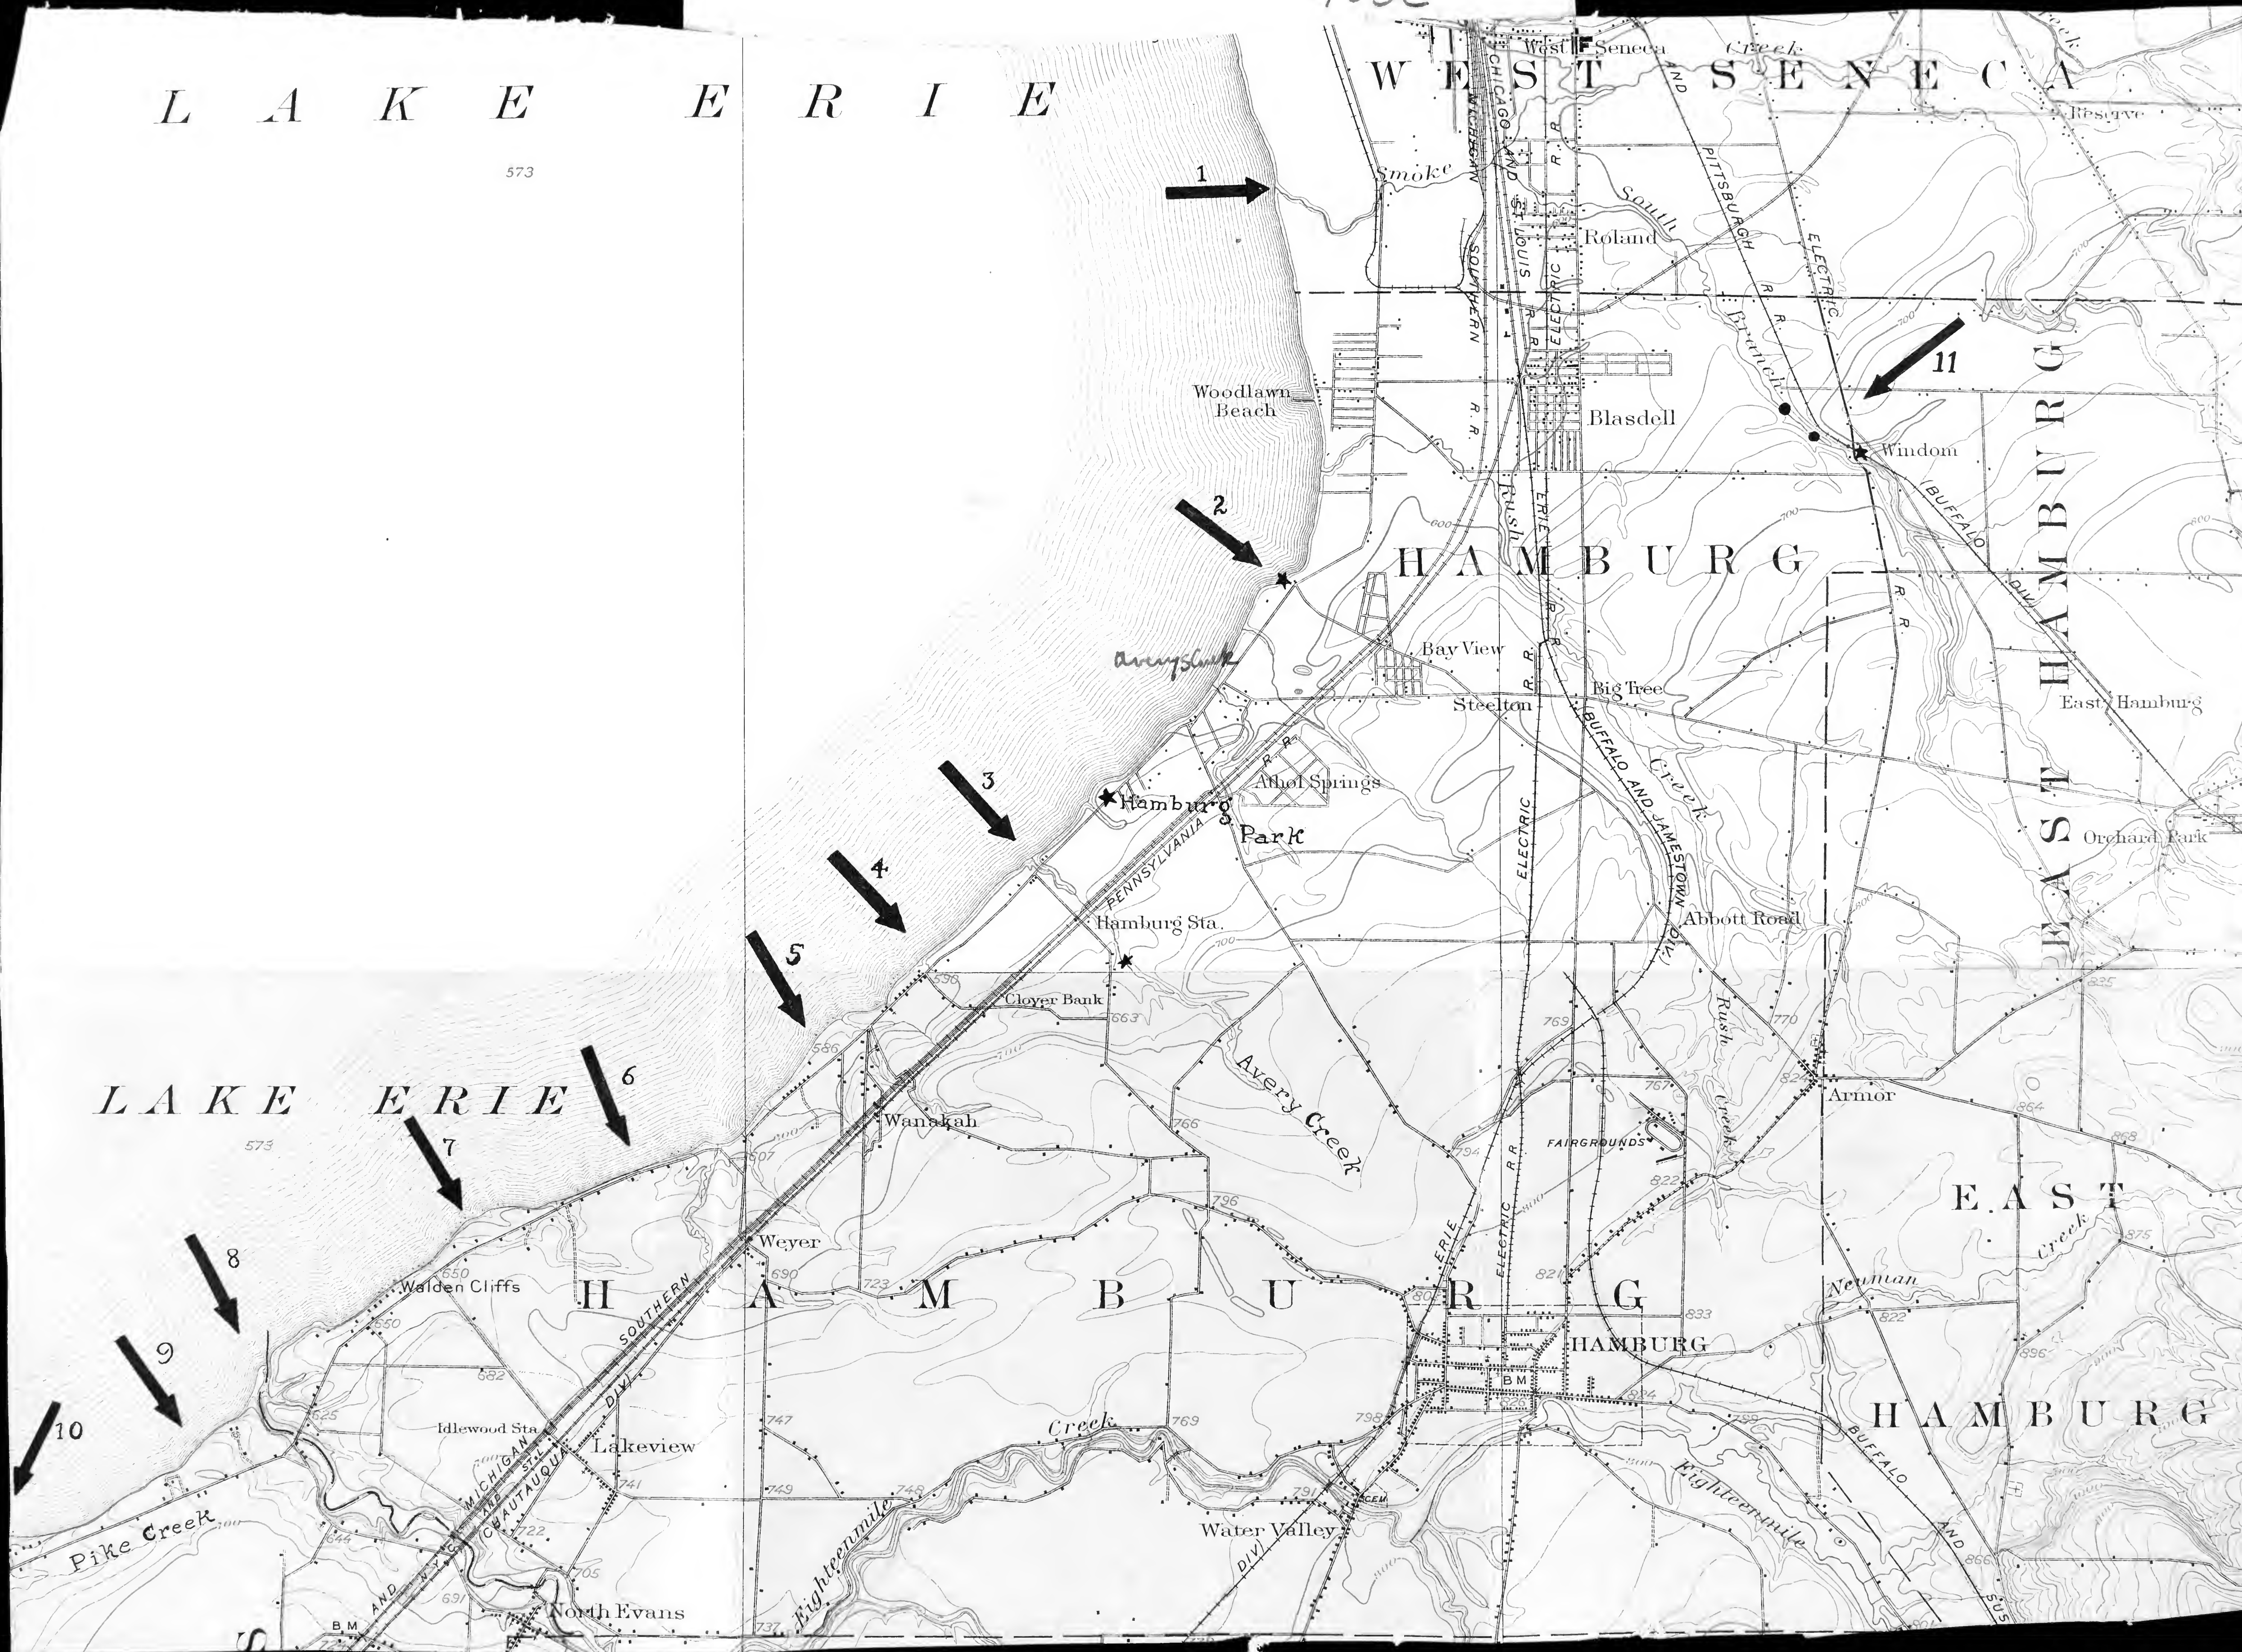

Applications for the separate topographic maps or for folios of the Geologic Atlas should

(printed in blue)

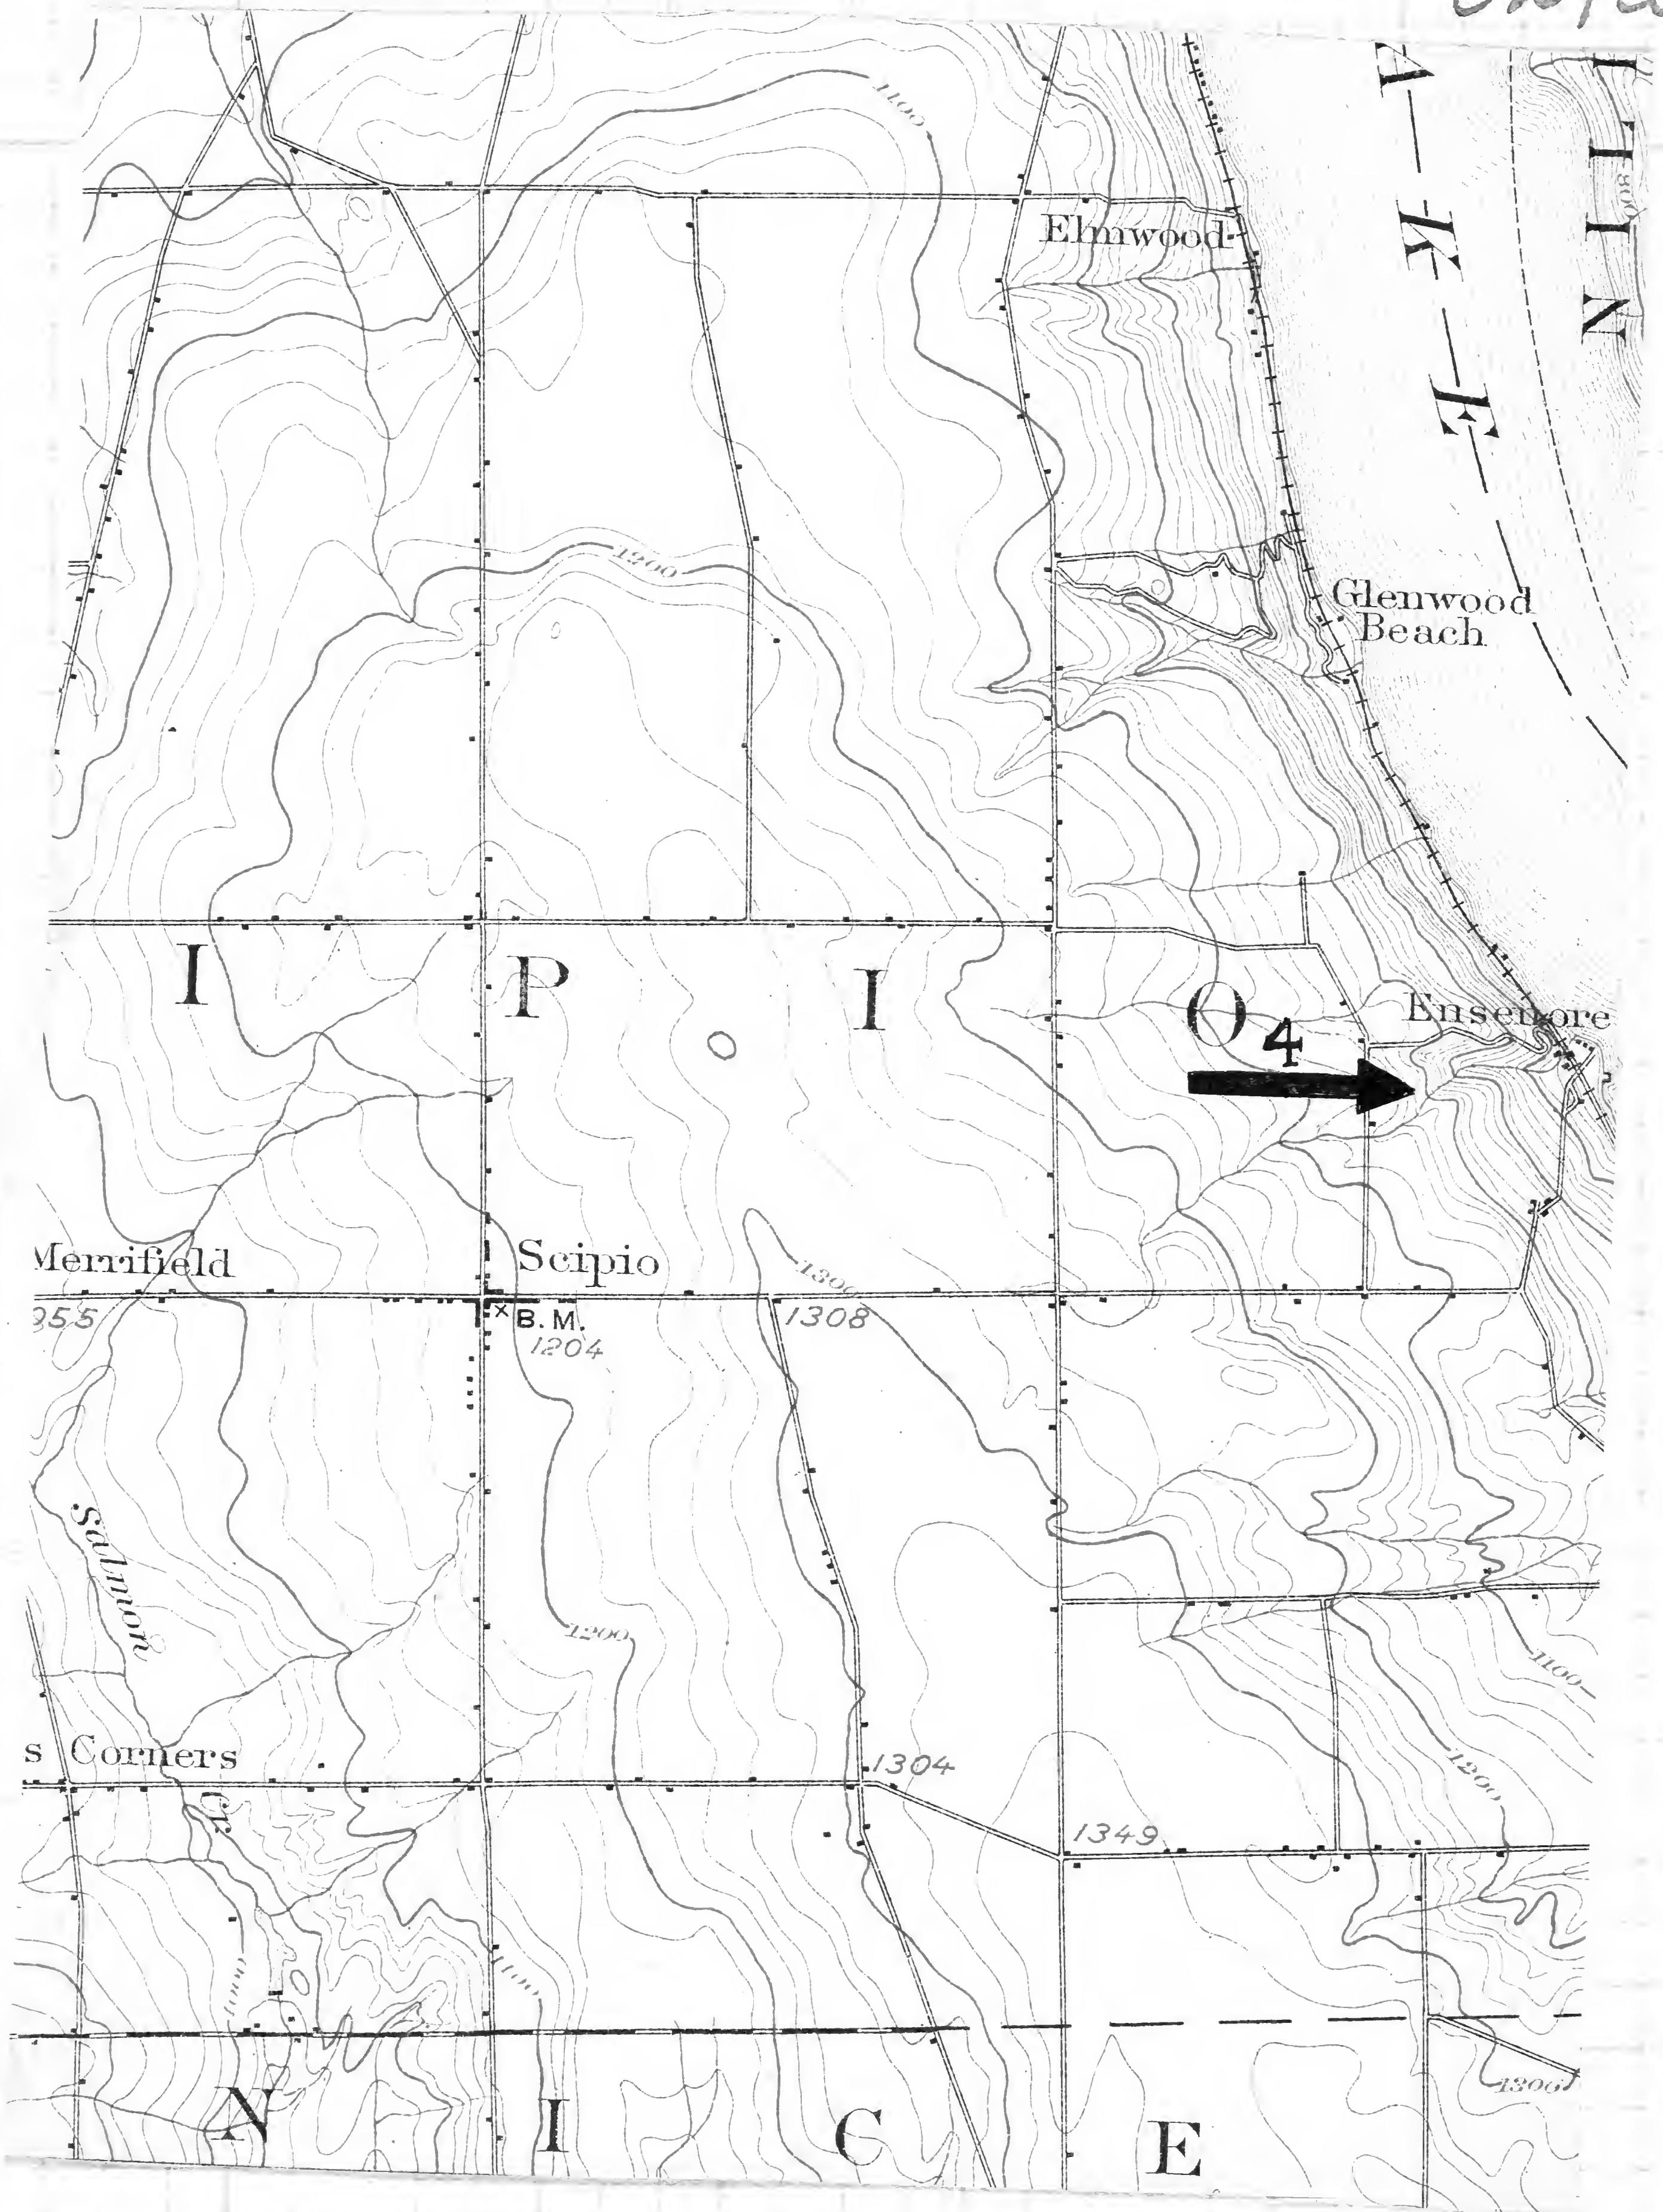

The United States Geological Survey is making a standard topographic atlas of the United States. This work has been in progress since 1882, and its results consist of published maps of more than 40 per cent of the country, exclusive of outlying possessions. This topographic atlas is published in the form of map sheets measuring about 16½ by 20 inches. Under the general plan adopted the country is divided into quadrangles bounded by parallels of latitude and meridians of longitude. The quadrangles are mapped on different scales, the scale being fixed for any quadrangle depending on its nature and its probable future development, and consequently though the

represents an imaginary line on the ground, the part of which is at the same altitude above sea level. Such a line could be drawn at any altitude, but in mapping only the contours at certain regular intervals of altitude are shown. The line of the seacoast itself is a contour, the datum or zero of altitude being mean sea level. The 20-foot contour, for example, should be shown as a line if the sea should rise 20 feet.

gradually away and forms an inclined table-land that is traversed by a few shallow gullies. On the map each of these features is represented, directly beneath its position is a sketch, by contour lines. The contour interval, or the vertical distance in feet between one contour and the next, is stated at the bottom of each sheet. This interval differs according to the topography of the country mapped; in a flat country it may be as small as 1 foot, in a mountainous region it may be as great as 250 feet. On the contour lines, every fourth or fifth one, are made heavier than the others and are accompanied by figures showing altitudes. The heights of many points—such as road corners, surfaces of lakes, and bench marks—are also given on the

329a

August 17.

Encore Ravine

81 paces from the railroad tracks on the point and directly behind the old Encore farm house is a falls and an exposure of shales in the bottom of the falls. The shale here is micaceous and soft. It is dark blue grey and has many fossils:—

| | |
|------------------------------|---------------------------|
| <i>R. fimbriata</i> | <i>A. spiniferoides</i> |
| <i>R. concentrica</i> | <i>C. bellistriata</i> |
| <i>Lox. hamiltoniae</i> | <i>G. reticularis</i> |
| <i>P. roma</i> | <i>S. pinnatus</i> |
| <i>L. densa</i> ✓ | <i>S. antostreatus</i> |
| <i>U. triqueter</i> | <i>C. bowthii</i> |
| <i>C. induta</i> ✓ | <i>Paracyclas lineata</i> |
| <i>C. mucronatus</i> | <i>A. decussata</i> |
| <i>A. umbonata</i> ✓ | <i>Aulopora</i> sp. |
| <i>M. pygmaea</i> ✓ | <i>P. bowensis?</i> |
| <i>P. crenistria</i> | <i>Platyceras</i> sp. |
| <i>M. subalata</i> ✓ | <i>S. rectum?</i> |
| <i>M. concentrica</i> | <i>Ap. coral.</i> |
| <i>P. flabellum</i> ✓ | <i>S. granulosa</i> |
| <i>Cyrt. hamiltonianus</i> ✓ | <i>S. andersoni</i> |
| <i>P. constrictus</i> | <i>C. vicinus</i> |
| <i>U. arguta</i> ? ✓ | <i>Par hamiltoniae</i> |
| <i>S. cheunigensis</i> ✓ | <i>S. cephalus</i> |

The fossils occur usually in layers of irregular extent, sometimes quite calcareous from limonoid remains. This is the first occurrence of *P. flabellum* I have noted so far down in the section. The falls comes at about 105 paces.

In the next 5' of rock collecting is not so easy. The shales are a dark

blue grey and rather massive giving
no effervescence with acid. The following
forms were observed: -

S. perplana *S. submarginata*
C. mucronatus c
C. coronatus
Pal. concentrica
Prod. cf. spinulicosta
P. rana
D. arcuata

Between 10' 10" & 15' 15" the shales are rather
hard, medium blue grey and calcareous.
They are like those seen on Bloomer Cr.
Indeed large blocks in the stream, filled
with *Trematis* are exactly like those on
Bloomer.

15' 15" - 20' 20" - a loose piece here contained
D. sculptilis *R. cyclos*
S. carinatus *C. mucronatus*
S. inaequistratus *Cran. hamiltoniae*
A. fenestrellid

Other fossils at this level are: -

Pal. plana

The brink of the falls is at about 30' above
the 81st page. At about 35' up a slab
was found that contained *S. carinatus*
in great abundance, *Cran. hamiltoniae*,
D. sculptilis, *S. inaequistratus*, *Platyceras* sp.,
H. bellistriata, *S. arctostriatus*, *S. perplana*,
C. setigerus, *Pan. hamiltoniae*, *Rhipidomella* sp.,
M. concentrica,

This was essentially a calcareous lens
and as far as I can see is identical
to similar lenses, which are given
because the matrix is sandier, at
Fertland Stock Farm.

The rock in the face of the falls from
25' - 27' is a hard calcareous shale
like most of that at Bloomer. At 27'

a rather large cup coral was discovered about 38 paces above the brink of the falls the following were noted:-

| | |
|-------------------------|--------------------------|
| ✓ <i>R. fimbriata</i> | ✓ <i>D. caninus</i> |
| <i>P. rana</i> | <i>Camarotoechia</i> sp. |
| <i>Pal. concentrica</i> | <i>Par. hamiltoniae</i> |
| <i>E. itys</i> | ✓ <i>D. sculptilis</i> |

Grammysia sp (small)

From the Brink of the falls to 229 paces above the same brittle shales are traversed varying but slightly & usually in line content & degree of hardness.

Fossils noted in addition to those recorded above are *N. oblongatus*, *S. granulosus*, *L. delia*, *P. stylopore*.

At 229 paces is a very fossiliferous layer of the shales a foot below carry small concretions, fossils here are:-

| | |
|-------------------------------|----------------------------|
| ✓ <i>D. caninus</i> c ✓ | (<i>D. truncata</i> rrc |
| <i>N. concinna</i> c ✓ | <i>S. andaculus</i> E |
| <i>Par. hamiltoniae</i> rrc ✓ | <i>B. crenistria</i> rrc |
| <i>P. rana</i> rrc | <i>S. inaequistriata</i> r |
| <i>N. oblongatus</i> r ✓ | <i>M. mytiloides</i> r |
| <i>Pal. concentrica</i> rrc ✓ | <i>V. pustulosa</i> ? |

| <i>Cran. hamiltoniae</i> r | |
| <i>C. mucronatus</i> (7) ✓ | |
| <i>R. varicosa</i> rrc ✓ | |

Terebratulids

N. varicosa rrc ✓

Cyclonema sp. rrc

C. bellistriata rrc ✓

D. sculptilis rrc ✓

R. fimbriata rrc ✓

N. bellistriata r

M. concentrica rrc

For. hamiltoniae r

Aviculopecten sp r

A. spiriferoides rrc ✓

A. decussata rrc

The horizon with *V. puatuloa* is about 23-25' above 1st Fall.

This division is approximately 21' above the brink of the falls.

At 250 paces comes a calcareous lens abounding in *S. granulosa*. Other fossils are:-

- | | |
|----------------------------|-------------------------|
| <i>M. concentrica</i> | <i>A. spiniferoides</i> |
| ✓ <i>C. scitulus</i> | <i>P. patulus</i> |
| <i>M. mytiloides</i> | ✓ <i>D. carinatus</i> |
| ✓ <i>D. sculptilis</i> re. | <i>Cyclonema</i> sp. |
| <i>Gon. hamiltonensis</i> | ✓ <i>S. andaculus</i> |
| ✓ <i>N. concinna</i> | <i>A. decussata</i> |

At 278 paces another zone is like that above having *S. granulosa*, *S. andaculus*, *M. mytiloides*?, *V. pustulosa*, *S. perplanus*, *D. carinatus*, *R. vanuxemi*, *M. concentrica*, *A. spiniferoides*, *N. concinna*, *Poriformis*, *C. coronatus*, *N. truncata*, *P. stylipora*, *P. rana*, *A. decussata*, *D. sculptilis*, *R. vanuxemi* — contains considerable pyrite. On top of the shales at 278 come the black shales with *L. laura*.

Other fossils at 278 are *S. obsoleta*, *N. oblongata*, *Selmerella*, *N. varicosa*, *Orthis*?, *A. spiniferoides*?

At 569 paces the land-level is reached on a high falls. Fossils noted in these shales are:- *Anopora* sp., *M. subalata*, *S. permatu*, *L. laura*, *P. rana*, *C. boothi*, *N. trigonatus*, *N. corbuliformis*, *C. bellistriata*, *L. laura*, *S. subalata*.

Fauna 21' 8" above 569 pace:-

- | | |
|--------------------------|-------------------------|
| <i>C. bellistriata</i> c | <i>A. spiniferoides</i> |
| <i>P. discordum</i> | |
| <i>N. corbuliformis</i> | |
| <i>M. subalata</i> c | |
| <i>A. umbonata</i> | |
| <i>Lox. hamiltoniae</i> | |
| <i>N. lirata</i> | |
| <i>Orthis</i> sp. | |

$$\begin{array}{r} 9 \\ 96 \\ \hline 105 \end{array} \quad 121$$

$$\begin{array}{r} 105 \\ 21 \\ \hline 126 \end{array}$$

32' up were found *P. spinulicosta*,
L. laura, *C. bellistriata*, *P. discoidium*
 and *Orthoceras* sp. At about 44' up in
 dark blue gray shales the following were
 found:

S. rectum, *Pal. concentrica*, *O. parvula*,
 Between 48 & 54' the following were
 seen: - *M. subulata*, *L. laura*, *S. pennatus*,
S. minimum, *Cyclonema* sp.,

Between the 10th & 11th steps (54-60' up) the
 following were seen: - *M. subulata*, large,
S. pennatus (very long winged), *M. triquetrum*,
M. oblongatus, *Orthoceras*.

At 59' 9" *Pal. concentrica*, *S. pennatus*,
G. subulatum, *S. pennatus*, *C. elongata*,
A. spiniferoides, *M. oblongatus*, *S. minimum*,
B. leda, *P. fragilis*, *P. radiata*, *A. umbonata*,
J. submarginata, *S. concava*.

Fauna between 18-19 steps: - 113'

A. spiniferoides

Pal. tenuistriata

S. pennatus

C. setigerus

Pal. concentrica

M. oblongatus

M. pygmaea

The shales here appear more
 massive and have so since the 11th
 step. Shales like this & with a similar
 fauna are present in Pattersons Glen
 on the Morrisville Grad.

The top of this unit falls is at 116'
 and here a hard layer of coarse
 shale, non-calcareous forms. The falls
 fossils are not abundant here either.
 Those noted are: - *C. scitulus*, abundant,
C. bellistriata, *S. pennatus*, *A. spiniferoides*,
A. decussata, *S. pygmaea*, *Gomophora* sp.,
C. setigerus, *P. rana*.

The coarse, hard shale continues about
 3' above the falls where a softer stone
 is encountered.

$$\begin{array}{r} 23 \\ 5 \\ \hline 115 \\ 7 \\ \hline 124 \end{array}$$

9

$$\begin{array}{r} 130 \\ 10 \\ \hline 14110^2 \end{array}$$

At 126' above the 569 place in the cascade above the 2nd falls was noted a thin ss. band. Above this the shales become somewhat more fossiliferous. Below it they are rather hard, tho softer than those at the brink of the 2nd. falls. Fossils below these thin ss (1") were *S. pennatus* + *M. trigonatus* + *M. oblongatus*.

Above these ss at 130' above the 569th place came many *C. scitulus*, *I. submarginata*, *M. concentrica*, *S. pennatus*. At 141' 10" is a hard band about 10" thick that forms the 3rd falls or cascade above the 2nd falls. This band is hard and is calcareous in places. A concretionary mass in it contained *S. pennatus* in abundance and *C. scitulus* in abundance, *I. carinata*, a teretibrachid, *A. decussata*, *P. tenuis*?, *M. concentrica*.

In the shales below *C. scitulus* was common, broad-winged *S. pennatus*, + *O. carinata*.

Above this hard band at 141' ^{up above 569} the shales are much finer but the 10" of rock just on the hard band is calcareous + very fossiliferous. It contains *A. spinifer*, *S. rectum*, *C. boothi*, *S. macronotus*, *S. andaculus*, *S. concavus*, *C. scitulus*, *P. flabellum*?, *C. coronatus*, *A. decussata*, *M. oblongatus*, *P. concentrica*, *P. variegatus*, *P. rana*. In places this layer is a ls. made up mostly of fossils. *S. perplana*, *A. reticularis*, +

In the rock that succeeds this there are calcareous bands + lenses with many fossils. The fauna in the 5" 5" above the hard band noted at 141' above 569 place follows:

- ✓ *C. bellistriata* cc
- ✓ *Pal. concentrica* ^{constriata}
- ✓ *S. macronotus*
- ✓ *P. iowensis*
- ✓ *M. concentrica*
- ✓ *C. scitulus*

Much of the rock between 141 and 144' is calcareous.

P. rana

- ✓ *C. coronatus*

- A. spiriferoides* cc
- Orbiculoides* sp
- ✓ *M. pygmaea*
- ✓ *S. perplana*
- ✓ *S. macronotus*
- ✓ *S. andaculus*
- between 141 and 144'
- ✓ *M. oblongatus*
- ✓ *S. pennatus*
- S. rectus*

In the shales between 146' 5" and 151' 10"

- C. bellistriata* cc
- Rhipidops hamiltoni* cc
- ✓ *S. pennatus* cc
- ✓ *M. oblongatus*
- ✓ *P. radiata*
- S. cheungensis*
- ✓ *P. tenuistriata*
- P. discoidum*
- M. pygmaea*
- ✓ *Pal. constriata*
- Pal. concentrica*
- ✓ *M. varicosa*
- ✓ *M. triquetra*
- Lox. hamiltoni*
- B. leda*
- ✓ *P. tenuis*
- N. corbuliformis*

Between 157 & 173' above the 569th part the shales have become harder under the hammer, and at 173 the fauna appears to be changing. The fauna at 152 had many *A. spiriferoides* & *S. pennatus*. At 173' were noted -

- ✓ *P. flabellum* c
- ✓ *M. concentrica* cc
- ✓ *S. granulatus*
- Rhipidomella* sp.
- ✓ *P. oviformis*
- Pal. hamiltoni*
- Orbiculoides*
- ✓ *I. carinatus*
- ✓ *S. pennatus*
- ✓ *R. varicosa*
- ✓ *C. bellistriata*
- A. princeps*

Additional fossils noted between 173 & 180' are -

- P. radiata*
- C. scitulus*

- S. perplana*
- P. rana*

Increased abundance of *A. spiriferoides*

70
141

At 184' above 569 were found *S. demissa*,
S. inaequistrata and above here the
 shales seem to become much softer.
 Other fossils were *A. spiniferoides*, *C.*
C. bellistriata, *S. granulosa*.

At about 186' (2' above the 8th step above
 141) the rock is calcareous, made up
 mostly of fossils and forms a flat
 here undisturbed *Cran. harringtoniae*, *S.*
arcuata,

At 10 steps above 141' the shale is
 calcareous. Between 12 + 13 besides
T. carinatus + *T. acutus* only a
 spinifer like *S. Dullius* was noted.
 This condition was seen at Sheldrake
 The Tichenor comes at 211' above 569.
 + is a xln grey ls. on it are 5 1/2 - 6'
 of shale + ls. alternations but no
 attempt was made to collect these
 or the Tichenor.

The ls. on the Tichenor has:-

S. pinnatus
T. carinatus
H. dekanji

P. rove
Cam. Toechia sp.

Essamore.

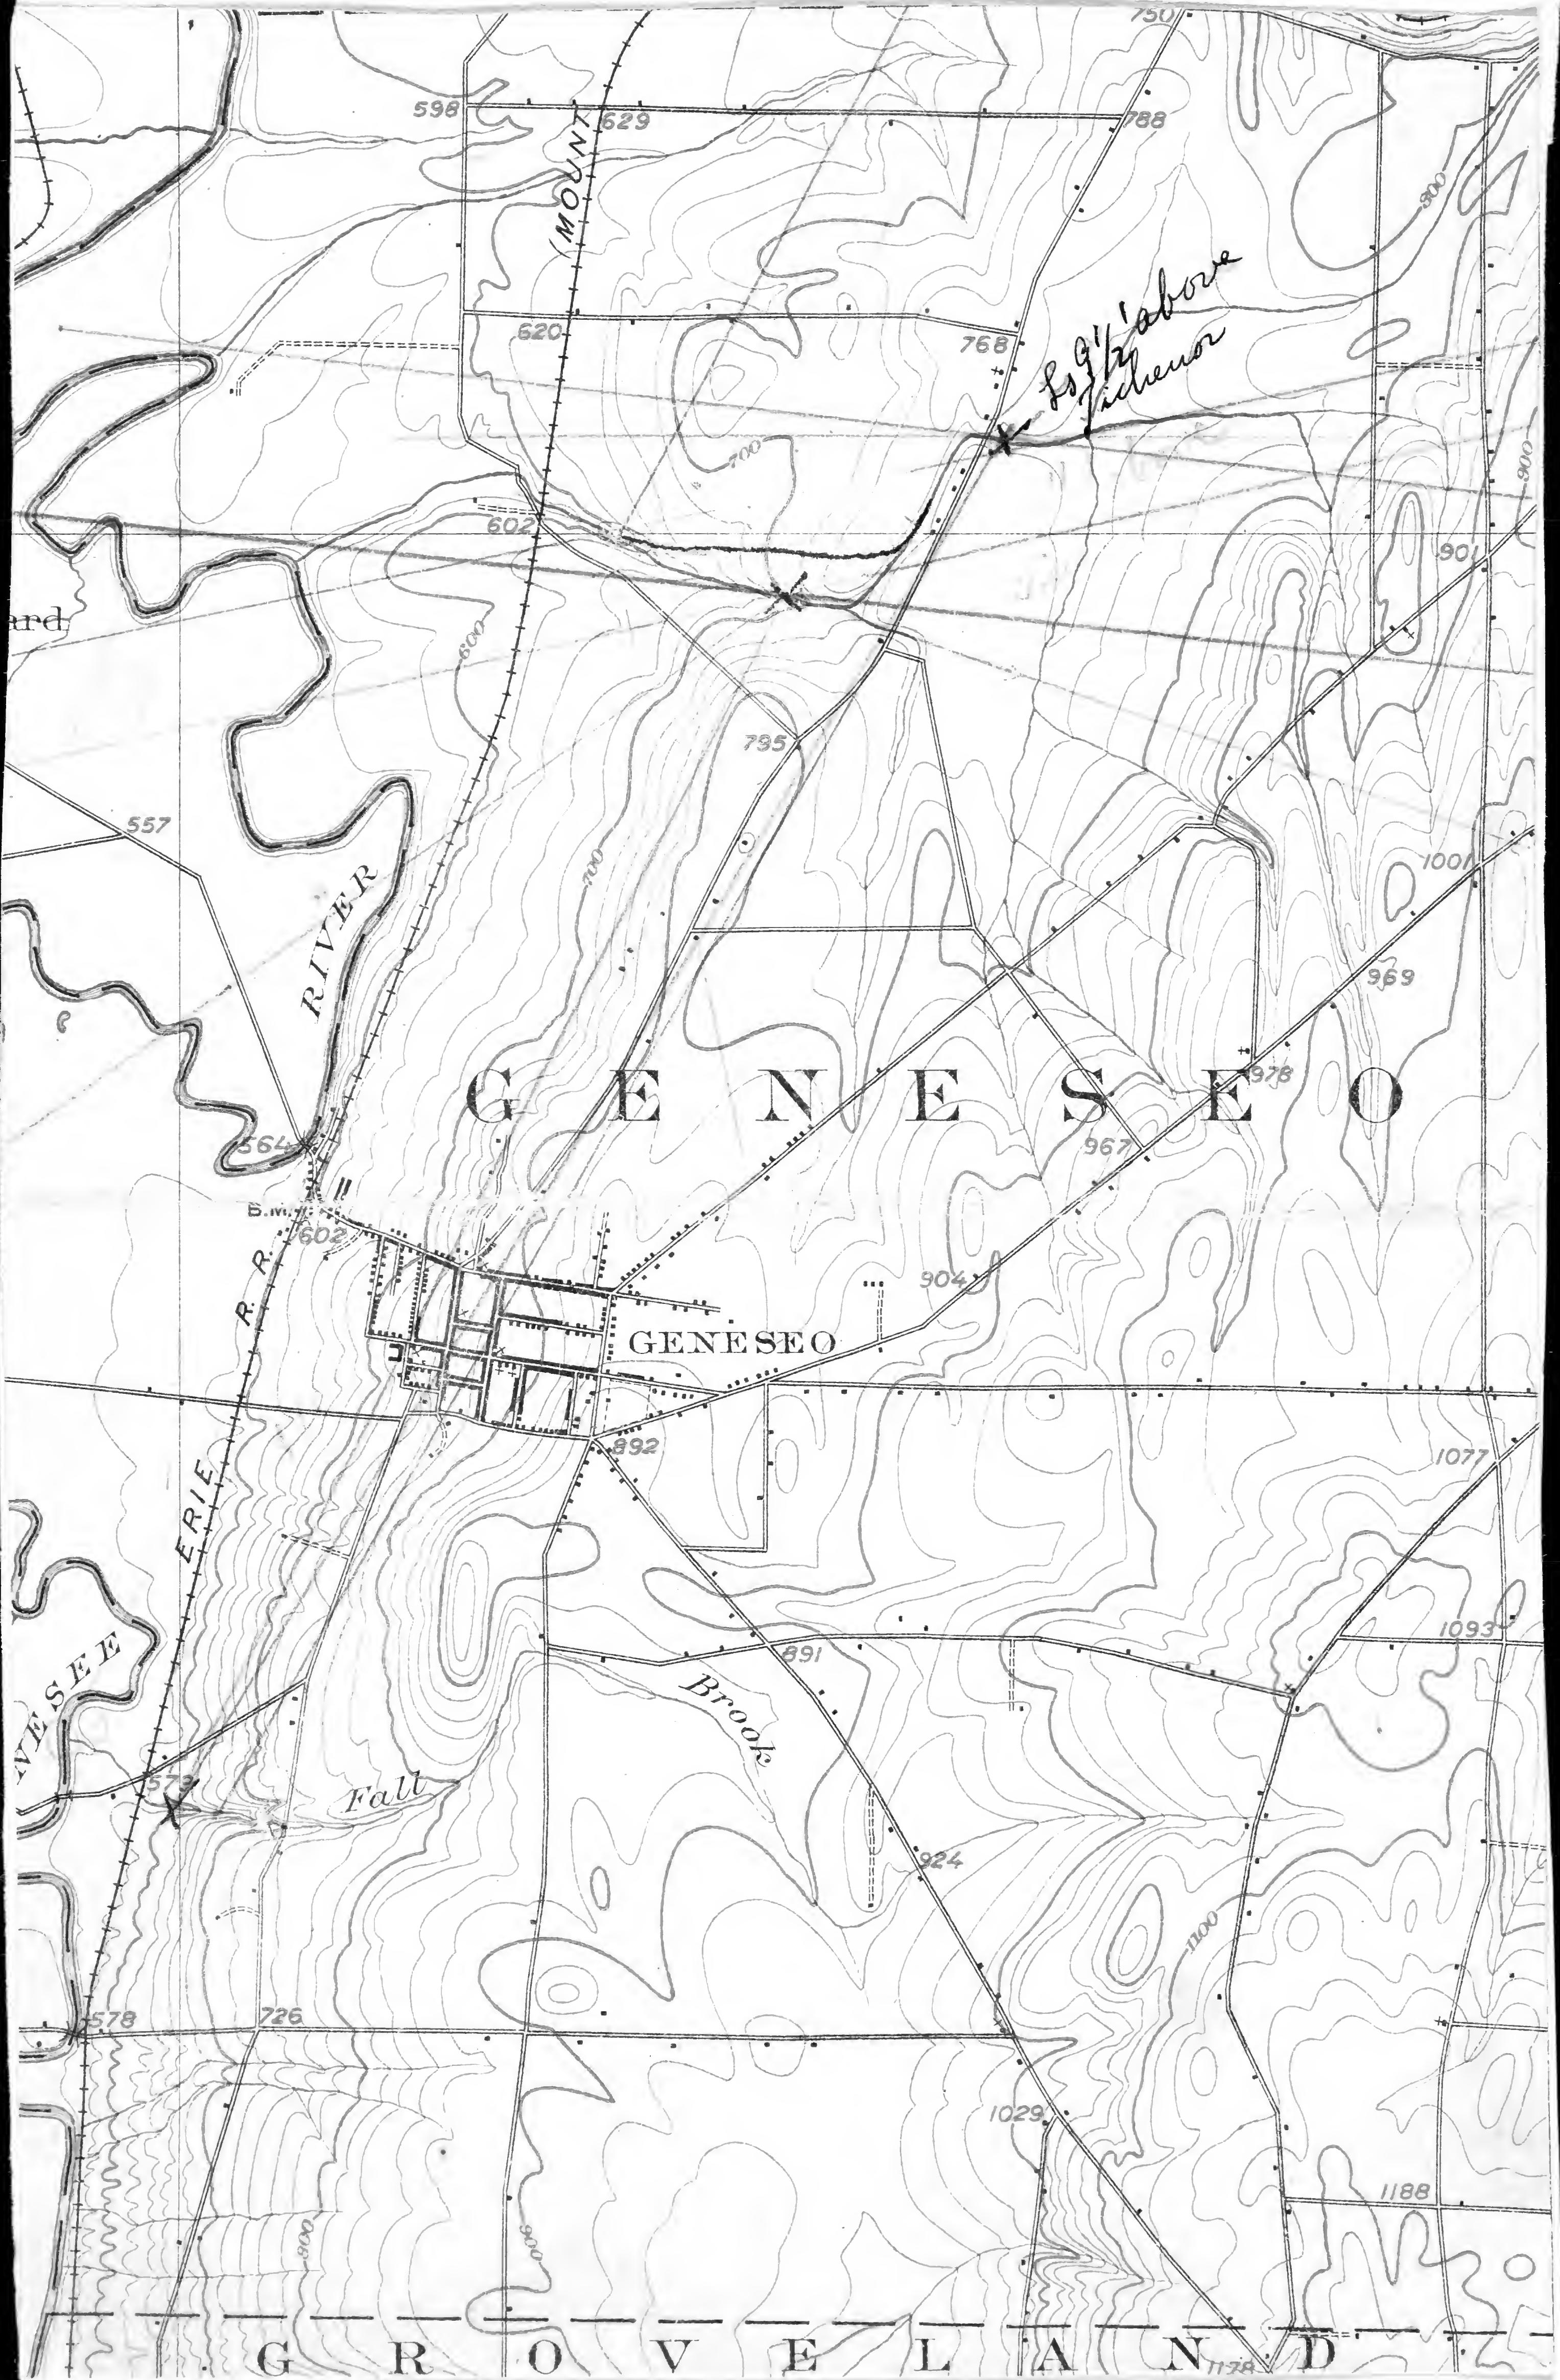

The lowest shales in Essamore and up to the dark shales, amounting to over 50' have a prolific fauna with a few corals, also *U. pustulosa* at the top. The Centerville must extend to yield the interval of shales from the top of the Shanoateles to at least the top of the Fertileland Stock Farm horizon. A few of the *Pelecypoda* found in the lower part of the Fiddlewille just behind the Old Essamore Glass House, such as *P. flabellum*, *P. luata*, & *Margarita* are very suggestive of the Geyser horizon.

The dark shale horizon seemed somewhat coarser and rather lighter than on the east side of Cayuga Lake. I suspect thickness could not determine, but it must occupy most of the red falls. A *spiniferoides* horizon in practically the whole of the upper part of the Fiddlewille.

Cleland's *Tellinopsis* zone I did not recognize. The strata below the Tichenor was quite barren but had *T. carinata*, & a *Spinifer* like *S. Tellus*. I did not recognize it. This condition was also noted at Sheldrake. The *S. demissa* and *P. flabellum* combination was also noted on Lake Erie.

Where *P. flabellum* came in and above this was a very noticeable falling off in the numbers and kinds of fossils.

338a

Fall Brook

At 225 paces from the intersection of the road with Fall Brook was found the first outcrop. This comprised about 100 yds. of bluish gray shale, in the strata high above the surface of the exposed bed. The surface of the rocks but in color was somewhat darker gray. They appeared to be from a region light gray shale. The dip given by actually measuring with a spirit level -

C. cuneata c.

C. cuneata c.

Cystodonta

C. angulata sp.

C. pinnatifida

C. setigera

C. undulata

Peristomatella (*Cystodonta*)

C. undulata etc.

H. deltoidea (*H. to arcata*)

H. deltoidea

P. stylonota (*P. stylonota*)

A. pinnatifida c. sp.

R. fimbriata

C. spiniferoides c.

Most of the fossils seem to be from the same horizon. The shale the most fossils to be found are - *C. cuneata*, *C. cuneata*, *C. pinnatifida*, *C. setigera*, *C. undulata*, *C. bellerophon*. These shales have much the same look as the Easton shales.

Proetus sp.

C. disjuncta

Bryozoa (abundant in patches)

M. uniformis

M. concentrica?

This bed must be the same horizon as *C. undulata* & *C. stylonota* in Fall Brook.

At 415 paces across a foot vertical of shale under an overlying band. These are somewhat more massive than those below as they break into large chunky blocks that yielded.

| | |
|---------------------|---------------------|
| <i>P. rana</i> | <i>P. rana</i> |
| <i>Pholidops</i> | <i>Pholidops</i> |
| <i>P. oblate</i> | <i>P. oblate</i> |
| <i>C. laticosta</i> | <i>C. laticosta</i> |
| <i>C. elliptica</i> | <i>C. elliptica</i> |

Continue with that below

At 445 paces well bedded concretionary shales gave *C. macrostoma*.

At 460 paces *Pholidops* shales gave the floor of the track. There are local *P. rana*, *P. bellatula*, *C. macrostoma*, *C. laticosta*, *S. parvulus*. *Pholidops* are in very great abundance at times picking up the entire rock. *Leptopora*.

At 625 paces we are still in the *C. laticosta* zone which is succeeded at 642 paces in the stream bed by a zone with large *Spinifer*, coral, *A. reticularis* and *A. spinosa*.

Additional fossils found in the *Anticollia* beds are:

| | |
|-------------------------|----------------------|
| <i>A. spiniferoides</i> | <i>C. coarctatus</i> |
| <i>Trachydictya</i> | |
| <i>Pal. coarctatus</i> | |
| <i>P. rana</i> | |

Range between 642 paces and 697 paces

At 697 paces a hard concretionary band of ls. crosses the stream bed and here forms a long flat on the track.

Range between *Anticollia* bed and

As one approaches the fossiliferous
the strata become more abundant and
near the top of the section was seen for at
least 1 ft. below the base of the base
of the *L. D. concolor* becomes
common in beautifully preserved
forms. Other fossils observed at
the contact with the *L. D.* and about
a foot below are:

- A. reticularis*
- Thyridina* corals
- A. spinifrons*
- P. rosea*
- S. pinnata*

Not a single *Ambracelia* has been
seen since the *Ambracelia* bed

Fossils observed in the 4' *L. D.* band
are:

- small corals. c.
- S. pinnata* (without points)
- P. terminata*
- C. viridula*
- P. rosea*
- Pal. concentrica*
- Schuchertella* sp.
- Conostrophia* sp.
- R. vancouverensis*

Resting at 740 paces

This fauna continues up for about 2 or 3 feet when the shales become sparser in fossils until 6' above the ls (4") band comes a layer with many corals as seen at Little Beach. Bellet with *Helophyton* and *Cyrtophyton*.

At 700 paces a corals and other stratum of the corals about 4' in thickness of the coral bed is at 5' above the 4" band and is a foot thick. It has *Bellet* and *Cyrtophyton*.

E. pinnatus

A. spinosa

R. concolor

About 1' above the coral bed was found

I. carinatus

A. spiniferoides

S. granulatus

S. inaequistrata

and for 1'

10' 10" above the 4" band comes *A. reticularis*, *R. concolor*, *Sheptelasma*, *R. decorata*. Below at 17' above the 4" band comes the second conglomerate band of ls. Below this band large *Spinifer* and *Cyrtophyton*. The contact with the Genesee is exactly 8' 10' 10" above the second ls. band at 700 paces.

The falls is at about 890 paces.

The upper concretionary layer has
a reticularis,

Fall Brook could

At the falls the lower 20' are Moscow but
are not favorably exposed for collecting.
However collecting is favorable above the
upper ls. ledge on the south side of the brook
where the ls. itself, which is a hard grey ls.
carries *A. reticularis*, *P. rana*, *F. cristatus*
A. spinosa.

On the concretionary ~~ls.~~ limestone
occurs a layer of light ~~ls.~~ of a calcareous
shale, quite hard with some rounded
fragments and other fossils. Below this
is the sand.

A. reticularis

A. spinosa

A. spiniferoides

P. rana

Bygonia

Aviculogaster

The shale for about 5' above the
concretionary ls. is light grey. ~~That about~~
This shale contains

C. indenta

A. reticularis

C. bruthi

P. rana

M. subumbona

Bygonia

Shale 4' below the pyrite contains
pyrite concretions sometimes many of
these pyrite masses are pyritized
shells and in this case are *Psaronius*
and a *Pleuronomaria*. here also 2
lingulas were found and some
large spinifers

In the shale just below the coral bed and on the zone containing the abundance of *Large Spinifers* occurs another with the following species:-

L. laura

Orbiculoides

A. procumbens (Lager)

The upper ls. is one that is very distinct and here can be followed with great ease.

Several distinct zones are here recognizable:-

1. There is a *C. corollarius* and *A. spinosus* zone below the lower ls.
2. In the lower ls. lies a zone with many large *Spinifers*, *L. laura*, *Platystrophia* etc. This gives way to a zone ^{also *Platystrophia*} <sub>*P. angulata*
P. truncatella
P. parvifrons</sub>
3. With *L. laura* and *Orbiculoides* and this to
4. The coral zone with *Cystophylloids*, then
5. Fossils like those on the lower ls. (zone 2) are found till the upper ls. is met.
6. Fossils like zone (2)
7. Somewhat barren shales with pyritized snails, bryozoa and an occasional large *Spinifer*
8. Pyrite.
9. *Hemerosa*

Below the *corollarius* zone an *Orbiculoides* zone could be recognized and considerably below this one with many *C. corollarius* & *Orbiculoides*.

On the stream-bed about 100 yds below the falls is a large concretion caliche but containing a layer of pyrite 1" thick and two feet in one direction and 3 in the other at pt 45. clt contains large sponges and cup corals. clt in in the zone on the lower ls and about 3' below the coral bed.

From 455-465 pages 6" of calcareous sh carries an abundant fauna:-

| | |
|---------------------------|-------------------------|
| <i>P. rana</i> cc | <i>A. densa</i> cc |
| <i>Fenestellidae</i> cc | <i>C. izdanta</i> r |
| <i>Platysma</i> cc | <i>P. lumbata</i> r |

Yellow Falls.

The hard band just below the
 coral bed contains *A. reticularis*, *C. recurva*,
C. congesta, *R. spiniferoides*, *C. recurva*,
S. granulosa.

On the coral bed the shales
 have *C. bulliata*, *C. L. L.*, *C. spiniferoides*, *S. granulosa*.
 Looked up this side the bed
 facies which is part of Clarendon which
 passes into the first *Strophomena* zone
 with *S. L. L.*

The sandstone is about 200
 below the bed of rock as indicated on
 the map.

Bear Mtn.

In the fauna of the shales with
S. L. L. the hard band may
 be added *Ph. L. L.* *Strophomena*

At 80-80 above the hard band are
 the *Cratopora* reefs. *A. reticularis* occurs
 also *P. L. L.*

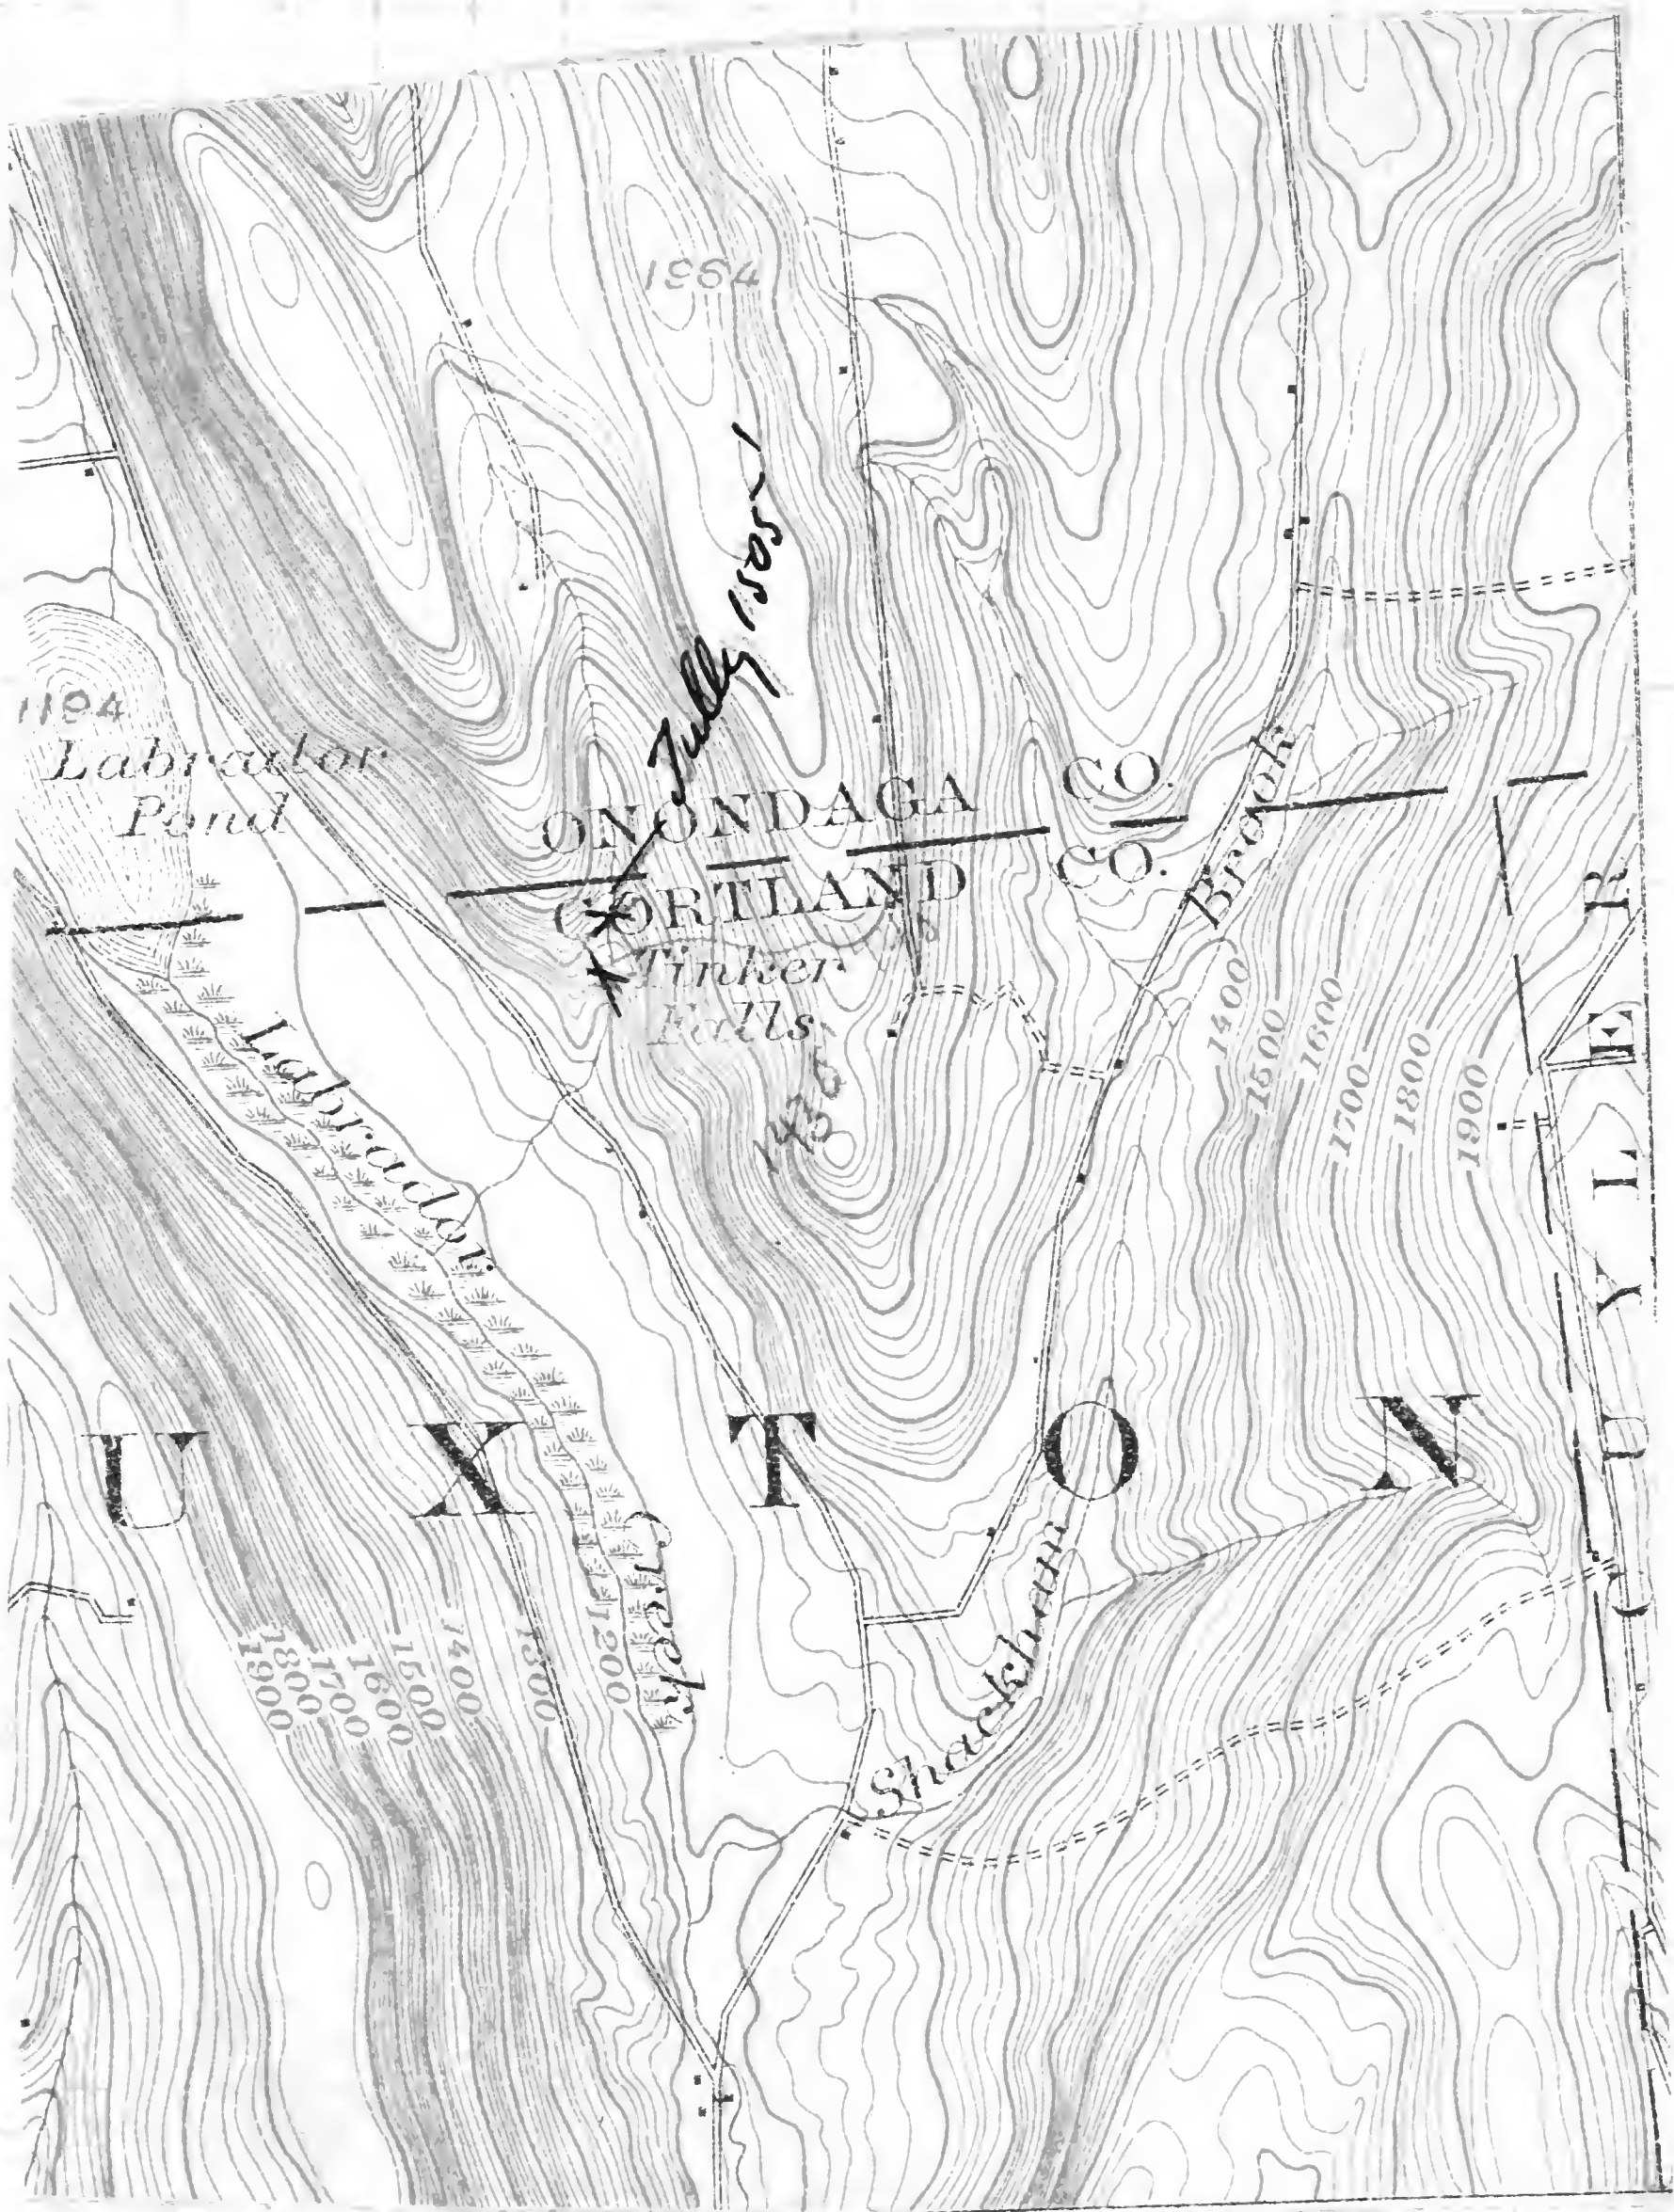

The *Cratopora* beds are about 6'
 thick. They also have *Strophomena* and
 also massive *Bygonia*.

Fossils 5' above hard band

M. arguta

A. princeps

352a

Timbers Falls.

1 1/2 mi. NNE of Tuxton, Cortland Quad, N.Y.

At 425 paces upstream we see a hard and heavy band of a blue-gray color. This gave slight appearance of with a red. Fossils in this are: *Spermata*, *C. umbonata*, *S. gran. lani.*, *P. vanuxemi*, *T. carinata*, *E. bellistriata*, *S. rugosa*, *S. crotonum*, *A. reticulatus*, *S. tullius*, *S. ap. p.*, *S. chrysomela*, *S. maculata*, *S. planus*. The rock below for 1 1/2' is a soft shale.

At 525 paces, rock is exposed in the stream. Here the following fossils were found:

| | |
|------------------------|-----------------------|
| <i>M. concentrica</i> | <i>S. carinata</i> |
| <i>A. reticulatus</i> | <i>A. reticulatus</i> |
| <i>R. punctatus</i> | <i>R. punctatus</i> |
| <i>P. carina</i> | <i>P. concentrica</i> |
| <i>S. granulatus</i> | <i>C. mucronatus</i> |
| <i>P. carina</i> | <i>M. agassizii</i> |
| <i>S. crotonum</i> | <i>P. laevigata</i> |
| <i>S. punctatus</i> | <i>Goniophora</i> sp. |
| <i>C. bellistriata</i> | <i>N. oblongatus</i> |
| <i>O. parvula</i> | <i>P. hamiltoni</i> |
| <i>Cystodictya</i> | <i>E. punctata</i> ? |
| <i>Pholidops</i> | <i>Cyrtolites</i> |

This fauna is for the first 3' of rock exposed.

1' above 525' is a hard band about 3" thick which contains *S. lania*, *M. subumbona* (or *A. pseudumbona*), *S. tullius*, *C. mucronatus*, *P. vanuxemi*, *Pal. concentrica*, *A. reticulatus*, *S. punctatus*, *A. spiroidea*. Just below the hard band the little shales have *S. lania* and *S. tullius* etc., also *T. carinata*, *C. mucronatus*, *H. capillaria*, *M. laevigata*.

26
33
59

65'

M. bellistriata.

The next 4 1/2' of shale are soft and break easily. They are also dark & contain *L. lauralis*, *R. praeumbosa* & *S. submarginata*, *M. oblongatus*.

The *R. praeumbosa* seems only to range for about 3'. The *Leiorhynchus* & *S. Tullius* are very large.

10'10" - 15'12" — same soft shale, with *M. oblongatus*, *Pal. concentrica*, *C. spinifrons*, *M. subulatus*, *C. indenta*, *S. acutus*, *S. crotalum*, *R. vanuxemi*, *A. reticularis*, *L. lauras*, *M. bellistriata*, *Pholidops*, *Par. ham*, *Lox. sp.*, *C. tetraceras* sp., *H. lute*.

15'15" - 20'10" — fine sand & earth, and
20'20" - 25'25" — the shale at the top of this interval has concretionary filling with small, also *S. Tullius*, *M. bellistriata*, *R. vanuxemi*.

25'25" - 30'30" — Blue gray shale with *C. scutulus*, *M. ashi*, *M. leiorhynchus*, *S. acutus*, *M. oblongatus*, *S. pennatus*, *Par. ham*, *Lox. sp.*, *C. tetraceras*.

30'30" - 35'35" — Blue gray pyrite — with *M. mytiloides*, *L. pennatus*, *Pal. concentrica*, *C. scutulus*.

35'35" - 40'40" — Blue gray shale

40'40" - 45'45" — same

45'45" - 50'50" — the blue gray shales in these intervals are quite sandy and fossils are abundant only in patches. Between 45'45" & 50'50" were noted *C. incisa*, *C. bellistriata*, *Trigula* sp., *Pal. concentrica*.

concretionary band

Blue gray arenaceous shales, 33'

bottom of falls.

L. orbiculatus, *Emella* sp., ?, *P. minutus*,
A. goniatites, *S. pinnatus*.

At 50' 50" another band layer of
 large concretionary or rock probably
 concretionary. In places the ls. is
 shaly but there are many
 concretionary pieces of pure ls. This
 contains abundant *S. crinitus*.

On this (50' 50" - 55' 50") comes 2' 8" of
 hard grey-blue sandy shales. It contains
A. spiriferoides, small black concretions.

55' 50" - 60' 60" - On this come very
 dark argillaceous shales which
 continue to the base of the gully.
 This shale is almost black, breaks into
 small flakes, and has practically no
 grit. It is in marked contrast to
 the lighter shales below. Fauna of
 18' 5' of dark shales: -

- | | |
|------------------------------|-----------------------|
| ✓ <i>S. pinnatus</i> (large) | ✓ <i>V. pustulosa</i> |
| ✓ <i>M. corbuliformis</i> | <i>M. pygmaea</i> |
| ✓ <i>L. laura</i> | <i>M. angustata</i> |
| ✓ <i>C. setigenus</i> | <i>M. elongatus</i> |
| ✓ <i>C. mucronatus</i> | <i>C. brevis</i> |
| ✓ <i>C. lapidus</i> | |

There are 2' 8" of these dark shales
 but only the first 4 or five feet and
 the last 5' are accessible for collecting
 fossils of the last 5' 5" are

- | | |
|---------------------------|-----------------------------|
| <i>M. vancosa</i> | <i>C. bellistata</i> |
| ✓ <i>S. pinnatus</i> | ✓ <i>C. incisurata</i> |
| ✓ <i>V. pustulosa</i> | <i>P. rana</i> |
| <i>F. nestled</i> | <i>A. retrahens</i> |
| ✓ <i>R. fimbriata</i> | <i>S. crinitus</i> |
| ✓ <i>S. andaculus</i> | <i>C. complanata</i> |
| ✓ <i>A. spiriferoides</i> | <i>L. laura</i> does not go |
- is confined to the last 5'
- up to the base of gully but

The shale here is transitional with the Jolly.

There is no sharp line here between the Moscow and the Jolly except one of weathering. At the line where the fissile shales are in contact with the calcareous shales of the lower Jolly there is a thinning zone weathering about 6" wide which follows the contact. On the dark Moscow comes a dark calcareous shale for three or 4 feet just above the first step of the Jolly. The rock was a hard little ls. The ls. forming the brink of the falls is flaggy and breaks into large slabs. This gives the whole mass the appearance of some of the weathered, slabby sandstone masses of the Hamilton. A peculiar reticulated texture was found in the shaley ls. at the contact. I make the Jolly here 31-32' thick. (copy)

Bucktail Ravine Spafford Valley

At the bottom of the ravine just upstream from the highway bridge are found sandy shales that become hard and form a 20 or 25' falls. In the lower part these sandy shales contain *M. subulata* + *L. clausi* somewhat higher up and about 15' below the brink of the falls *P. flabellum* was common. *M. pygmaea* was also noted. These shales have the look of the Red Gate horizon or U. Arany. On the brink of the 1st falls were noted *Schuchertella* c, *J. cuneatus* *Conarotocchia* sp.

4 steps above the falls there is a hiatus, then comes dark slightly sandy shales abounding in *Thomomys* and other fossils as follows:

| | |
|---------------------------|--------------------------|
| <i>S. ellipticus</i> | ✓ <i>J. cuneatus</i> |
| ✓ <i>S. cheunungensis</i> | <i>Crinoid stems</i> |
| <i>S. perrinites</i> | <i>Bryozoa (massive)</i> |
| ✓ <i>C. wisnisi</i> | ✓ <i>C. pectilatus</i> |
| <i>S. perversa</i> | <i>P. rana</i> |
| <i>C. bellistriata</i> | <i>Aviculopecten</i> sp. |

8 steps above the first falls is a small cascade over very hard ss. layers which has the following:

| | |
|----------------------------|-------------------------|
| <i>S. perrinites</i> | <i>S. granulatus</i> |
| <i>A. decussata</i> | <i>A. spiniferoides</i> |
| <i>Conarotocchia</i> sp. ~ | <i>J. cuneatus</i> VII |
| <i>N. concinna</i> ? | |

8-18 steps - hiatus

At the 18th step come coarse discolored shales, probably blue-gray when fresh with occasional fauna. They have

- | | |
|-----------------------------|-------------------------|
| ✓ <i>S. demissa</i> c. | ✓ <i>S. pinnatus</i> cc |
| ✓ <i>S. concava</i> | ✓ <i>A. reticularis</i> |
| ✓ <i>A. spiriferoides</i> c | <i>B. leda</i> |
| ✓ <i>S. periplaneta</i> | |
| ✓ <i>T. carinatus</i> re | |

Between 19 + 20 steps the following species are recorded in a dark slightly sandy shale: -

- | | |
|-----------------------------|--------------------------|
| ✓ <i>S. pinnatus</i> cc | <i>Burchiella?</i> |
| ✓ <i>A. spiriferoides</i> c | <i>A. princeps</i> |
| ✓ <i>H. oblongatus</i> | ✓ <i>R. vanuxemi</i> |
| ✓ <i>H. lineata</i> | <i>P. flabellum?</i> |
| ✓ <i>Pal. fenestrata</i> | ✓ <i>S. demissa</i> |
| ✓ <i>S. concava</i> | ✓ <i>C. bellistriata</i> |
| ✓ <i>S. mucronata</i> | <i>A. small coral.</i> |
| <i>A. decussata</i> | ✓ <i>S. periplaneta</i> |
| ✓ <i>S. granulosa</i> | ✓ <i>T. carinatus</i> |
| ✓ <i>Pal. maxima</i> | ✓ <i>Pal. constricta</i> |

At 23 steps comes a falls 15 or 20' high composed of hard sandy shales that break into large slabs which are difficult of fracture along the bedding plane. In these were noted

- | | |
|-------------------------|--------------------------|
| ✓ <i>T. carinatus</i> | <i>Cyp. tenuistriata</i> |
| <i>Pal. emarginata</i> | <i>M. guthriei</i> |
| <i>C. elongata</i> | <i>S. tullius</i> |
| ✓ <i>S. periplaneta</i> | <i>Pal. concentrica</i> |
| ✓ <i>S. pinnatus</i> cc | <i>A. spiriferoides</i> |
| | <i>Orthoceras</i> sp. |

One slab lying under the falls *P. flabellum* is very abundant. Other fossils noted in the slabs are:
P. sand
O. berys
M. concentrica

The falls is caused by a hard band with *S. concava*, *T. carinatus*, *Schuchertella* sp., *C. mucronatus*, *P. isomaris*, *P. flabellum*, *R. vanuxemi*

Camarotoechia sp., *S. perplana*, *Crinoid* stems. This band is quite calcareous & it is not directly on the brink of the falls but is about 19' to a foot thick and as upstream about 25'

On this hard band comes softer shales with abundant fossils:-

- | | |
|-----------------------------|---------------------------|
| ✓ <i>P. radiata</i> c | <i>Pal. hemisphaerica</i> |
| ✓ <i>S. pennatus</i> cc | ✓ <i>M. concentrica</i> |
| <i>B. leda</i> | ✓ <i>C. scitulus</i> |
| ✓ <i>M. pygmaea</i> | ✓ <i>C. bellistriata</i> |
| ✓ <i>M. globuliformis</i> | ✓ <i>N. lirata</i> |
| ✓ <i>N. triquetra</i> | ✓ <i>I. carinatus</i> |
| ✓ <i>Pal. hemisphaerica</i> | ✓ <i>S. perplana</i> |
| ✓ <i>A. spiriferoides</i> | ✓ <i>Triglophus</i> sp. |
| <i>Gymnogygia</i> sp. | <i>Orthoceras</i> sp. |
| <i>G. arcuata</i> | |

This layer at least in its lower part is characterized by the great abundance of *P. radiata*.

Another falls comes about 25' above the 27th step and here there is an overhanging shelf that allows examination of the shale just under the falls. It is dark grey and sandy. The following species were seen in it:-

- | | |
|-----------------------------|--------------------------|
| ✓ <i>C. bellistriata</i> | ✓ <i>N. bellistriata</i> |
| ✓ <i>I. carinatus</i> | ✓ <i>S. granulosus</i> |
| <i>Protolopidodendron</i> ? | ✓ <i>P. globellum</i> |
| ✓ <i>S. pennatus</i> | ✓ <i>M. concentrica</i> |
| <i>P. dekeyi</i> | ✓ <i>M. mytiloides</i> |
| <i>Cyclonema</i> sp. | |

The top of this falls is 160-165 and then comes another about 8 or 10' high. At 32+3 the rock is a hard sandy shale with the fauna given above. Then comes softer shale for 4' but they soon become sandy and heavy again to produce the cascade above.

the overhanging falls at 160-160.
Fossils in this cascade are:-

On the lower part
S. pennatus ! cc
M. concentrica
Pal. harringtoniae
A. erectum
A. spiciferoides

II

On the upper part - which is sandy
S. demissa *S. pennatus*
M. concentrica *A. princeps*
S. perplana *S. perversa*
A. spiciferoides

At 34 (170-170-1) comes the top of the cascade above the overhanging fall. This is succeeded by still another cascade. The top here is somewhat calcareous and produces the cascade.

At 35 comes another cascade about 20' high. Here from 34 to the top of it are blue grey shales. The fauna could not be examined as there was no good place for collecting. The following were noted however:-

M. oblongatus
S. granulatus

J. crenatus
C. scitulus
Pal. concentrica

I

The hard band forming this cascade is 28" thick. The 37th step came at the bottom of the hard band. It is hard & areaceous for 14" but quite calcareous for the other 14". Both layers gave effervescence with acid. Above this the shales are all blue grey and they go clear up to the Dully.

18-10-1904

My dear Sir,

I have the pleasure to acknowledge the receipt of your letter of the 10th inst. in relation to the above matter.

I am sorry to hear that you are not satisfied with the results of the examination. I have been very anxious to see that all the necessary precautions were taken, and I am sure that the examination was conducted in the most thorough manner possible.

I have been in communication with the authorities concerned, and I am sure that they will be able to provide you with the information you require.

I am sure that you will be satisfied with the results of the examination, and I am sure that you will be able to provide me with the information I require.

I am, Sir, very respectfully,
Yours faithfully,
J. H. [Signature]

The first 5' of shales contain
S. perplana ✓ *R. vanuxemi*
T. carinatus ✓ *P. fennelae*
P. rana ✓ *T. carinatus*
C. bellostriata
S. pennatus ✓
S. granulosus ✓

At 5' 5" there is a calcareous band
M. mytiloides, *A. spiriferoides*

At 10' 10" *T. carinatus* is common.
H. triquetra *S. pennatus*
Pal. constricta *S. tullius*

The shale between 10' 10" & 15' 15"
 is somewhat more massive
 than that below. Half way between
 15' 15" & 20-20 there is a thin
 calcareous band.

At 30-30 *A. umbonata*, *P. rana*,

Fossils in the 1st 10' of Moscow

B. leda
T. carinatus cc
S. pennatus cc
S. arenata

A hard nodular l. band is at 5' 5"
above T. The first 5' of rock is very
hard and difficult to collect. This
shale is rather sandy.

"Jackson" - 2 layers each $\frac{1}{2}$ " thick
containing many fossils. Below it
a siliceous - are Jackson band 14" thick

At the highway bridge at Spafford Valley are 25 or 30' of rocks that are sandy shales below and become coarse and slabby at the top of the falls. The exact place of these shales in the section I cannot place, but it must be in the vicinity of the coral bed horizon 43' above the first falls comes rather soft shales that bear *S. demissa* and *S. concava* in abundance. These should correlate with the rocks at the brink of the 2nd high falls in Fellows ravine. These shales become sandy and a hard band in them causes a falls, which should be the same as that on the sandstone layers at about 250-255 in Fellows Falls ravine. Then comes softer shales abounding in *P. radiata*, which become progressively sandier till they form a cascade, the water falling over a hard, slabby, heavy arenaceous rock. *H. delavayi* was noted here and *P. flabellum* was common. There follows about 4' of softer shale succeeded by another hard band as was seen just below the road bridge at Fellows falls ravine. This shorter interval is followed by soft bluish gray shales that culminate in a 28" hard band, the upper 12 or 14" of which proves to be the Tichenor. This then is the same sequence that was seen in the Fellows Falls ravine.

This ls. is not essentially the same as that noted in the Cayuga Lake section as it does not contain the great amount of crinoid debris seen at that place. It is light blue

grey in color and abounds in fossils.
366
366
At one place the cephalon and pygidium of *H. delany* was found in the rock.

On this limestone the shale is blue grey and rather hard for the first 5' 5" where a nodular band forms a cascade and 15' 15" above this another band forms a cascade. I had difficulty collecting these beds, hence the lists are meagre. *A. umbonata* comes in around 32' above the Tichenor and continues up to a point between 54 and 60' above the Tichenor. On this follows a zone with *S. rectum*, *Strophodontites* and *A. reticularis*, also *R. chrysocoma* in abundance. This zone continues for about 20-25'. Then come, in all probability, the shales of Cleland's *M. pygmaea* zone which is so well developed at Shurgers Glen. There is a 2' list of them in which the shales cannot be examined.

At the base of the falls, of which the Tully is the source, the shale is hard and practically no fossils could be collected from it. The only collecting done here was between 135-135 and 140-140 where *S. concolor* was found. This fossil was found below the Tully in Cleland's *Spinifer-Atrypa* zone at Cayuga. At about 155' above the Tully the shale becomes dark colored, friable and much like the Seneca up to the base of the Tully, about 8' in coll. The dark shales carried *S. carinatus* and *S. tuffus*. The Moscow section is essentially the same as that seen in Shurgers Glen.

August 20.

Yellow Falls

The first rock encountered was that about 300-400 yards below the falls. It was a very sandy rock, a clay as it were abundant and is the same kind as exposed in the upper part of the lower section.

Rock exposed practically at the end of the lower section, hard and forming a ledge 200 yards at the bottom of the falls is a rather soft dark shale with *P. fragilis* & *L. larva*, *H. tigris*, *H. tigris*.

At a top the latter is decidedly sandy. At 200 yards had *L. larva* and *P. fragilis* in abundance.

The rock 20' above the first stone exposed is hard and sandy shale but contains *L. larva* in some abundance.

20' up - *P. fragilis*, *L. larva*, *H. tigris*. Between 40-50 & 50-60 the same fauna exists. Rock is sandy with *C. tigris*.

At 65-65 - *L. larva*, *H. tigris*, *L. curvata*, *P. penetrans*, *Prodictella* cf. *spinulosa*.

Between 65-65 and 65-65 the rock is coarse and sandy. Between 65-65 and 65-65 the rock is medium to fine grained below the bedrock. Has some *Prodictella*, *P. penetrans*, large unguis and *curvata*, *Hesperia* sp., *L. larva*, *H. tigris*, *P. fragilis*, *Prodictella* sp., *C. tigris*, *Orthoceras* sp., *G. capillaria*, *P. litta*, *C. cf. tunicata*.

65-65 - 70-70 the shale is hard, massive sandy, gives no appearance except in the powder or on a crushed surface.

Between 20-20 and 25-25 the rocks become very calcareous and have a few small corals and fossils. This is also the very base of the fall.

Above the base of the fall were seen 9 or 10' of sandstone, rather heavy-bedded but ones that split into heavy slabs. There are occasional large spherical concretions. The only fossils noted in the beds lower are:

C. incompressa 7, *P. flabellum*, *Conocorynus*, *S. perplanus*, *C. micromatus*, *Cyst. hamiltoni*, *A. decussata*.

At 30-31 - the rock is composed of a softer shale abounding in fossils. The shale from 1 1/2' is rather hard and somewhat more massive than that above.

Fossils are:

- | | |

Character 2 sp.

✓ *F. stellatus*

The abundance of *S. divaricatus* here is very striking.

90-90-95-95 - In the stream bottom the same shales with bands composed almost entirely of *C. reticularis*. Also *C. complanata* and *Acanthopora* were noted here.

From 95-95-100-100 the rock is of course the same but about 10 ft. just below the falls fossils are *A. princeps*, *A. reticularis*, and *C. beuthi* were observed abundantly within 8 or 10' of the bottom of the falls. Other species observed are: *S. pinnosa*, *Ostracoderma* sp. & a large *Strophodont*.

At the top of the falls bed is at 130-130 - Corals the rock is of the Ludlowville. This 10' fall is caused by a hard sandy layer that contains *S. pinnosa*, *A. princeps*, *C. beuthi*. This hard sandstone band is 3 or 4" thick and cements the shales that contained *S. dimidiata* & *A. reticularis* in much larger numbers.

The coral bed is between 6 1/2' and 7 1/2' thick. It consists of a dark, rather soft shale in which the corals abound. *Leptæna* and *Cystiphyllum* are the commonest fossils.

The shales in the coral bed are a blue gray like our Earville shales and abound in *C. bellistriata*. Other fossils noted were:

M. subulata

H. ligata

L. laura

B. laura

C. bellistriata

H. corbuliformis

H. oblongatus

Ophoceras sp.

Pal. constricta

Right near the coral bed *A. spiniferus* and *S. pinnatus* were noted. A horizon with *C. bellistriata* and *S. edura* was found in the middle of the 100' falls at Ensenore. The *Cypicardella* come from about 15 or 20' above the coral bed.

At 180-190 the strata seem to be very fossiliferous and for some were observed:

C. boothi

H. oblongatus

✓ *S. pinnatus*

✓ *S. edura*

There are in a dark blue somewhat sandy shale.

Between 200-205 & 205-210 the following were seen:

✓ *A. spiniferus*

H. bracte

✓ *S. pinnatus*

H. oblongatus

80 *H. concinna* 30

R. lida

C. boothi

205
205
205

✓ *S. pinnatus*

Between 205-208 & 210-215 the following were seen:

R. cyclops

A. spiniferus

✓ *G. endotekta*

H. concinna

✓ *R. vanuxemi*

✓ *S. gr. lous*

✓ *S. pinnatus*

✓ *R. constructa*

✓ *H. oblongatus*

C. boothi

✓ *A. smalli*

✓ *S. concinna*

✓ *S. pinnatus*

✓ *S. pinnatus*

✓ *C. boothi*

✓ *S. pinnatus*

S. pinnatus

P. flabellum

✓ *A. decussata*

✓ *S. pinnatus*

This falls above the coral bed is fully 80' vertical. Beyond this is another smaller falls.

215-225-220-220 - coarse sandy loamy bedded shales with bryozoans.
P. flabellum, *I. curvatus*, *C. bellistriata*
 Long winged *S. pinnatus*, *M. concentrica*,
Pal. constricta, *H. oblongatus*, *C. f.*
scholastica,

220-220-230-230 - coarse shales breaking into large slabs. They have a prolific fauna -

P. flabellum ✓ *E. gracilis*
 ✓ *I. curvatus* cc *M. concentrica*
 ✓ *C. concentrica* ✓ *A. spinosides*
 ✓ *S. pinnatus* cc
Pal. emarginata

The *S. pinnatus* are very large indeed. The bed forming the first cascade here is not only sandy but is calcareous.

Between 230-230-235 is the only very hard sandy and fossiliferous large slab. The fauna found in this interval *S. pinnatus*, *Trigula* sp., *Fenestella* and the plumose of an *H. delongi*.

At 230-230-240 comes an extremely hard band about 1'-15" thick. It has fossils, *Spinifer* & *I. curvatus*. On this come dark soft shales. The sandy beds are 4" thick from the *Strophomena* beds. The upper thin are probably 15' of shaly ss beds and thus making 25' or 30' of ss.

The blue grey shales over the sandstones contain the following fossils - *I. curvatus*, cc, *H. oblongatus*, *C. scutellus*, *C. retigens*, *S. pinnatus*, *Pal. concentrica*, *H. linearis*, *H. varicosa*, *S. pinnatus*, *M. concentrica*, *H. trigonatus*, *C. bellistriata*, *Pal. pinnata*.

*C. coronatus**Sauropora* sp.*A. spiriferoides**Amulopeter* sp.

A little higher up the shales become coarser and break into chunky fragments.

*P. flabellum**Pal. emarginata**S. granulosa**S. costata**M. mytiloides**M. oblongatus**A. princeps*?*A. scitulus**S. blanda*

A thin band of sandstone at 255-255.

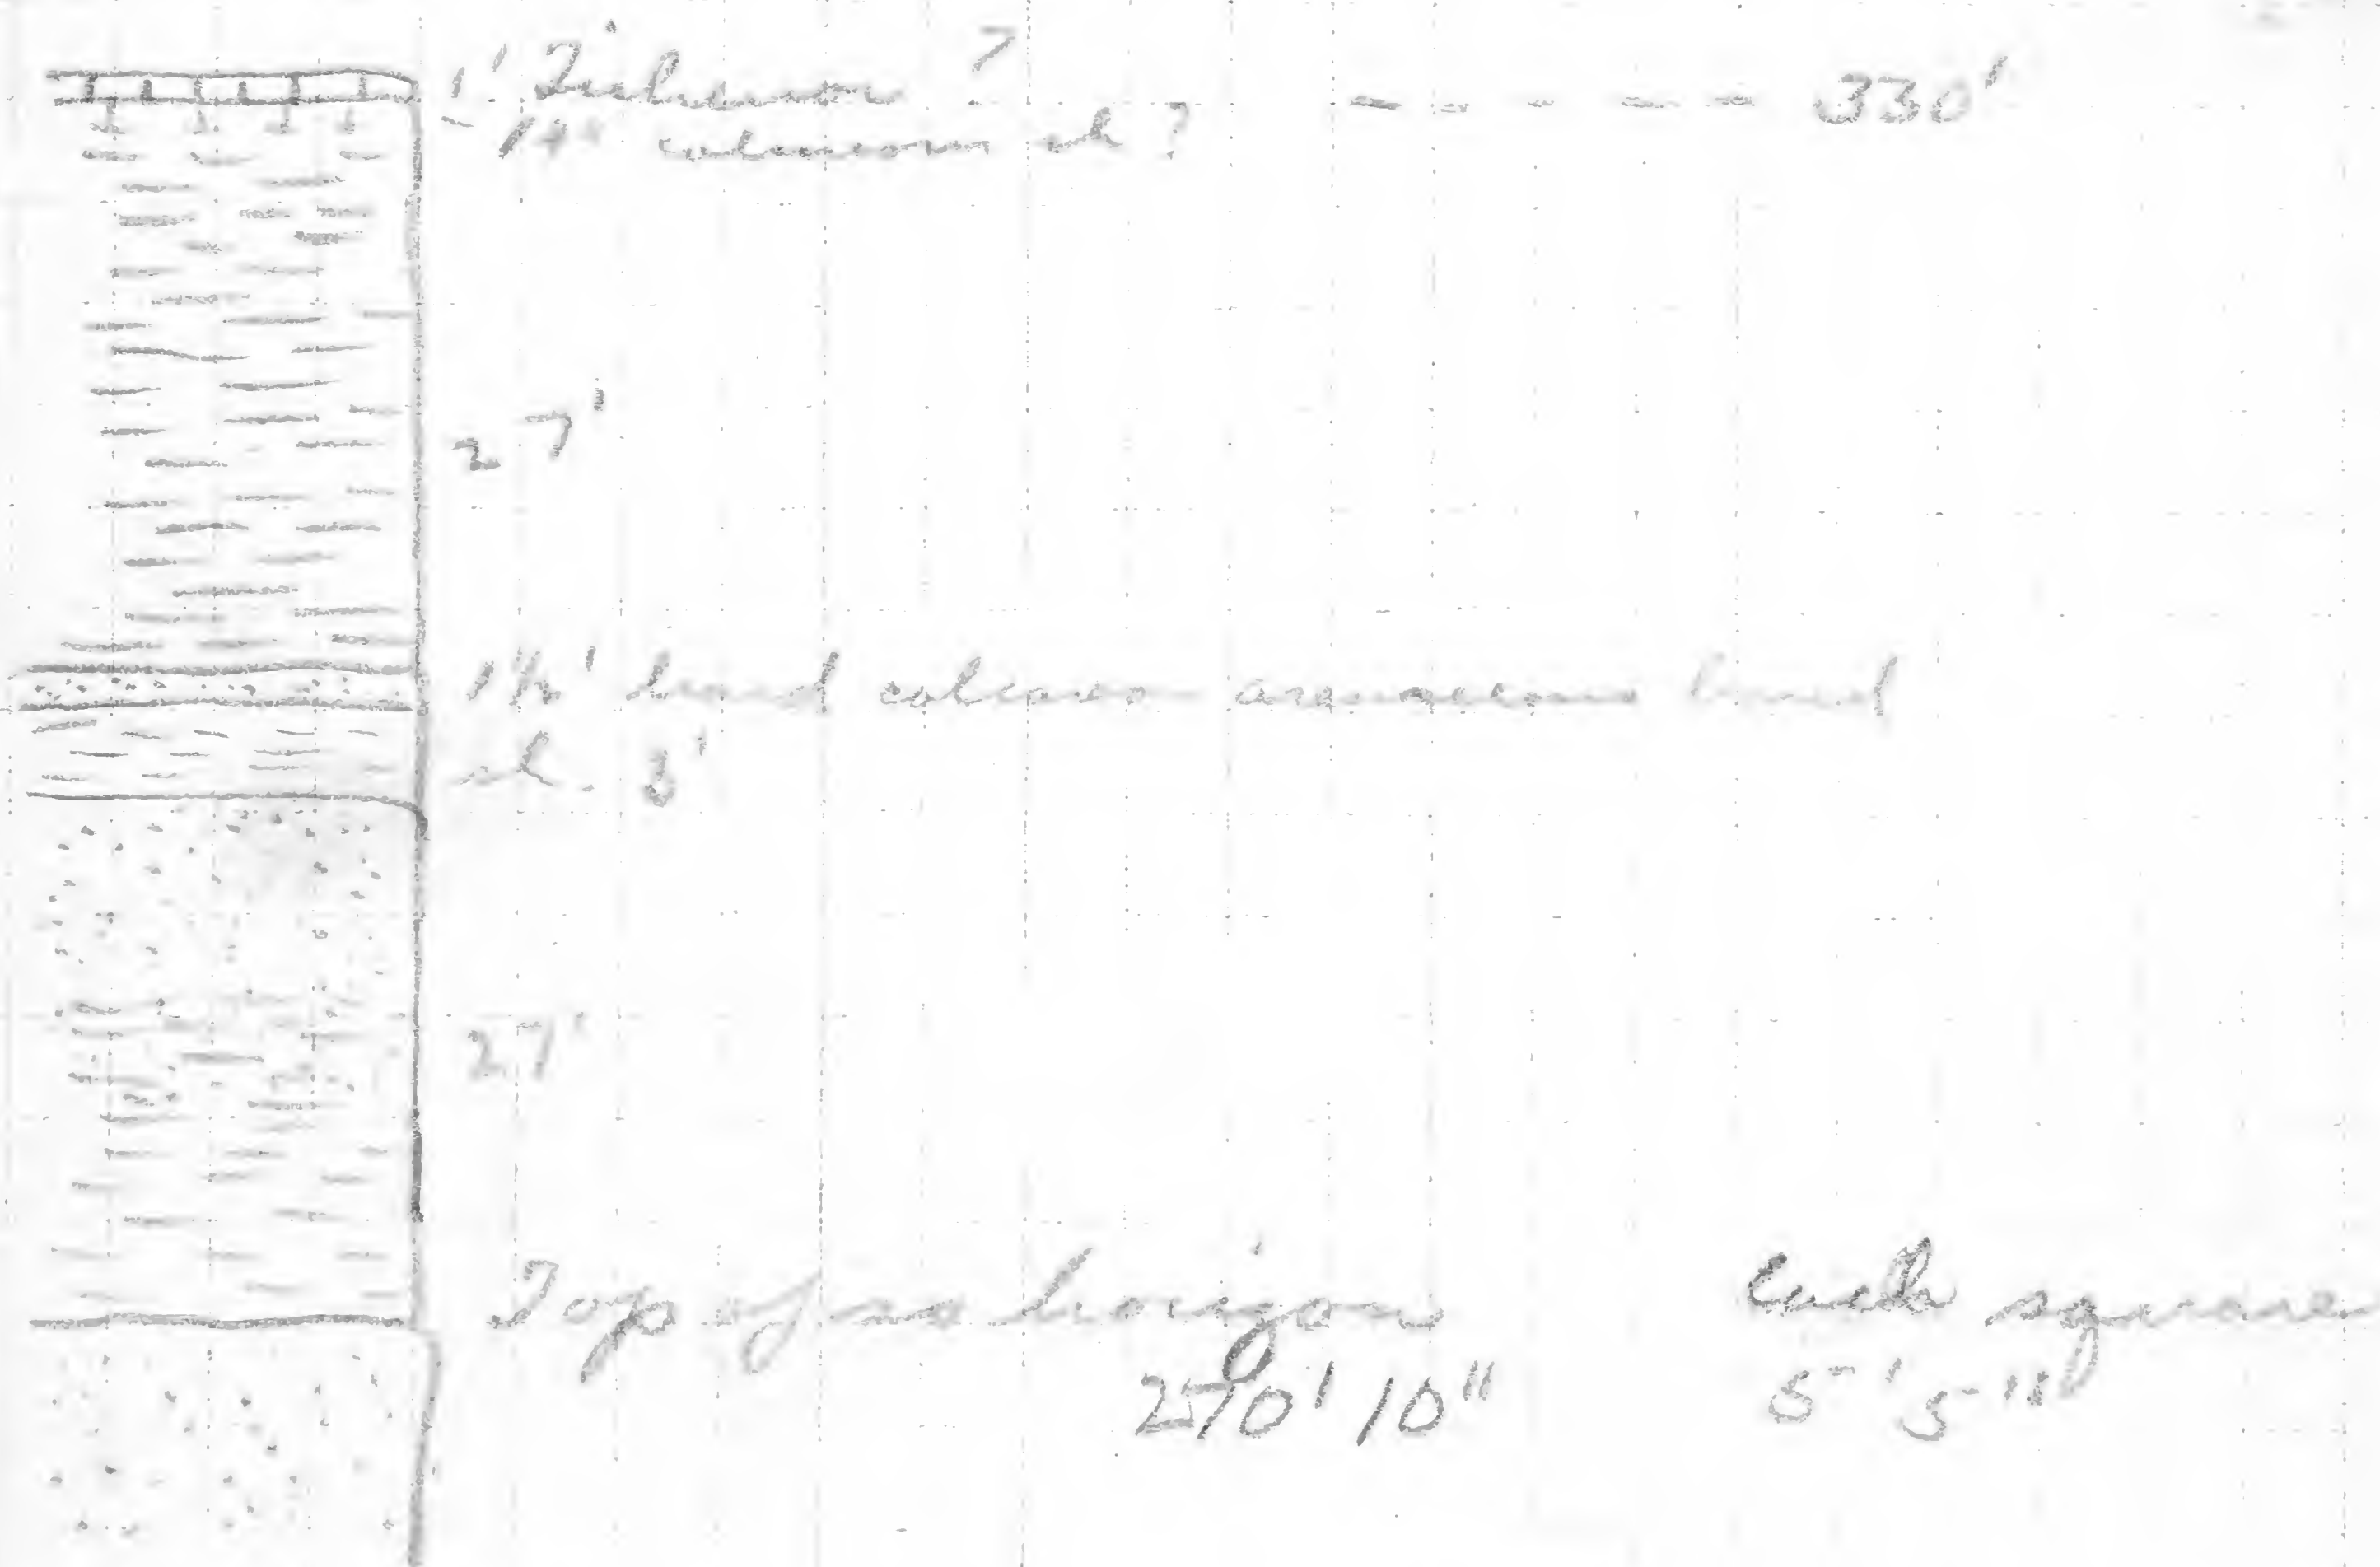

P. flabellum common at 255-255 in these shales where it is common and is associated with *Amulopeter*. Between 255-260 and 265-275 the shales become sandstone which are hard and break up into very large slabs. Fossils at 275-275 are *C. coronatus*, *S. costata*, *S. granulosa*.

About 200 yds upstream from the highway crossing are 15' of dark blue grey shales with many fossils and on top of these a 26" band of hard blue grey ls. This may be the Fishmore unit exposed on the map to west of the highway.

The bluish shales contain:

C. bellistriata ✓*Pan. hamiltoniae**S. granulosa* ✓*A. costata**Pal. emarginata* ✓*Pan. hamiltoniae**S. granulosa* ✓*M. oblongatus**S. parvata* ✓*M. concentrica* ✓*A. scitulus**Leptotermis* sp.*P. radiata* ✓*S. parvata* ✓*M. bellistriata* ✓

Section at Falls below
highway bridge & also west of it.

The ls. crosses the stream in ~~a~~ an 8 or 10' cascade 300 paces from the highway bridge. The rock is very fossiliferous and contains many Crinoid stems. It also has:-

I. carinatus

S. pinnatus

C. scintillans

At the falls the ls. bed is about 1' thick.

The 300 paces upstream represents 27' by level.

at 280³-280+2 comes the top of the rock below the highway. This makes a total of 303

The falls at the top under the bridge is caused by a hard calcareous ~~arenaceous~~ band in two layers 9" thick each. Below it are about 3' of dark bluish grey shales. This hard rock contained *S. pinnatus*. Two large slabs below the falls and probably from this horizon contain:-

S. pinnatus

H. deflexa

I. carinatus

S. per plana

C. coronatus

S. cf. Idemissa (?)

A. princeps

I believe on looking at the ss beds again that they begin as near as at 230-235 and go up to 250-250 minus 2', and thus are about 19 or 20' thick. They probably belong to the University Quarry horizon.

Below the ss are sandy shales which continue down to the *Strophodont* band at the top of the big falls above the coral.

horizon. Below this to the coral beds the shale is less sandy and may belong to the lower *Strophomena* shales in Patterson's Glen or Randallville Gorge.

The shale with *S. demissa* and *C. bellistriata* continues to 225-225-230-230 as representatives were found here. Above this come the ss. which are shaly for 5 or 10' judging by their weathering, but become flabby at around 235-235

Section of first falls

Remarks on the Ludlowville

Before coming to the falls, the sandy beds that break into thin layers and appear so much like fissile shales were noted. Then there is a hiatus until practically the end of the reach in fact. Actually the stream crosses the road, although it is not indicated on the maps, and just beyond the crossing are found dark soft shales, undoubtedly belonging to the Shanesetites. These shales / distinct "Shanesetites of the west" aspect. The fauna continues as a typical Leontynechus fauna for about 65' from the bottom at the Mill house where the first soft dark rocks were met. At this level *L. curtum* was found and with *L. gemmatus*, *P. linearis*, *E. capillaris* but also *L. linearis*. About 25' up the shale is a ss and continues so for 15' or 20'. At the base of this ss is where *L. linearis* the line should be drawn although Luther does not say in his text just where the line is drawn. It is possible that it is drawn at the sandy beds below the dark Shanesetites but this is not likely. No collecting could be done in the ss.

On the ss comes a soft shale abounding in *S. divaricatus* and other fossils. This may be where the Hyman quarry enters, if it is not Shanesetites. Above this shale comes a hard band and then the coral bed. On the coral bed, which forms the base of the second large falls, the strata

are blue gray and about 10' above the corals also in *C. bellistriata*. The fauna of this falls could not be examined except at the top & the bottom, as the face of it could not be scaled. On top of the falls *S. dimissa*, & *S. concava* were found. This layer with *Cypripedellus* below & *Strophodonta* above is between 100 and 105' thick. On this comes about 20' of sandstone with spherical concretions & *P. flabellum* which are probably in the same horizon as the *M. Anany* and they looked like that stone. Then comes a soft shale that passes into a sandstone, 32', on this soft shale again with a prolific fauna 27' and this is capped by a hard band of ls. a foot thick. This stone appears thicker downstream due to calcareous shale band below. This ls has not the *S. S.* of the Tichenor elsewhere but has some of its fauna. It is the first stone in which *Camerozouchea* were seen in any abundance.

On Tuttle's Bar 230' of concretion are represented in the Ludlowville. My measurement is 230' by level & is probably wrong. It is impossible to tell just how far down this line of it is when the strata below become sandy it would add 60 or 70' to the measurement.

S. dimissa was only found in the lower 2 or 3' of the shale in which it occurs. *A. reticularis* ranged up to 10 or so feet of the coral bed. There are difficulties in assigning this to the

New Gym horizon.

I noticed no beds with many *Camarotoechias* or small *Spirifers* as we have them in Madison Co. The zone with *E. linklaeni* was not seen, nor anything like the Centerfield ls, unless the beds with *S. divanicatus* and *A. rethraonis* be it. The coral bed would properly go with the Centerfield equivalents, and the shale at top would go with the Patterson's glen fauna. It will be noted that in some ravines at Erieville *S. demissa* with a *Leiorhynchus* fauna was found. The *Gym* beds, and the "Electric light" stream horizon are still mysteries. I do not believe that they are blackwaters for I have seen zones in the blackwaters with *H. arguta*, large *Spirifers*, *P. laticosta* & others more commonly seen above. The beds from 250-250 minus 2 up to the "Lichenor" (?) I believe belong to the Red Gate horizon.

Sept 4.

About 2 miles E of Keeny on the opposite side of the Valley (East) is a quarry about 15' thick of soft, dark blue-grey shales. The fauna indicates that the beds are in one of the Amboceras zones.

The rock crumbles easily into small irregular, cherty fragments.

August 23, 27.

Road between Jamesville + Martins

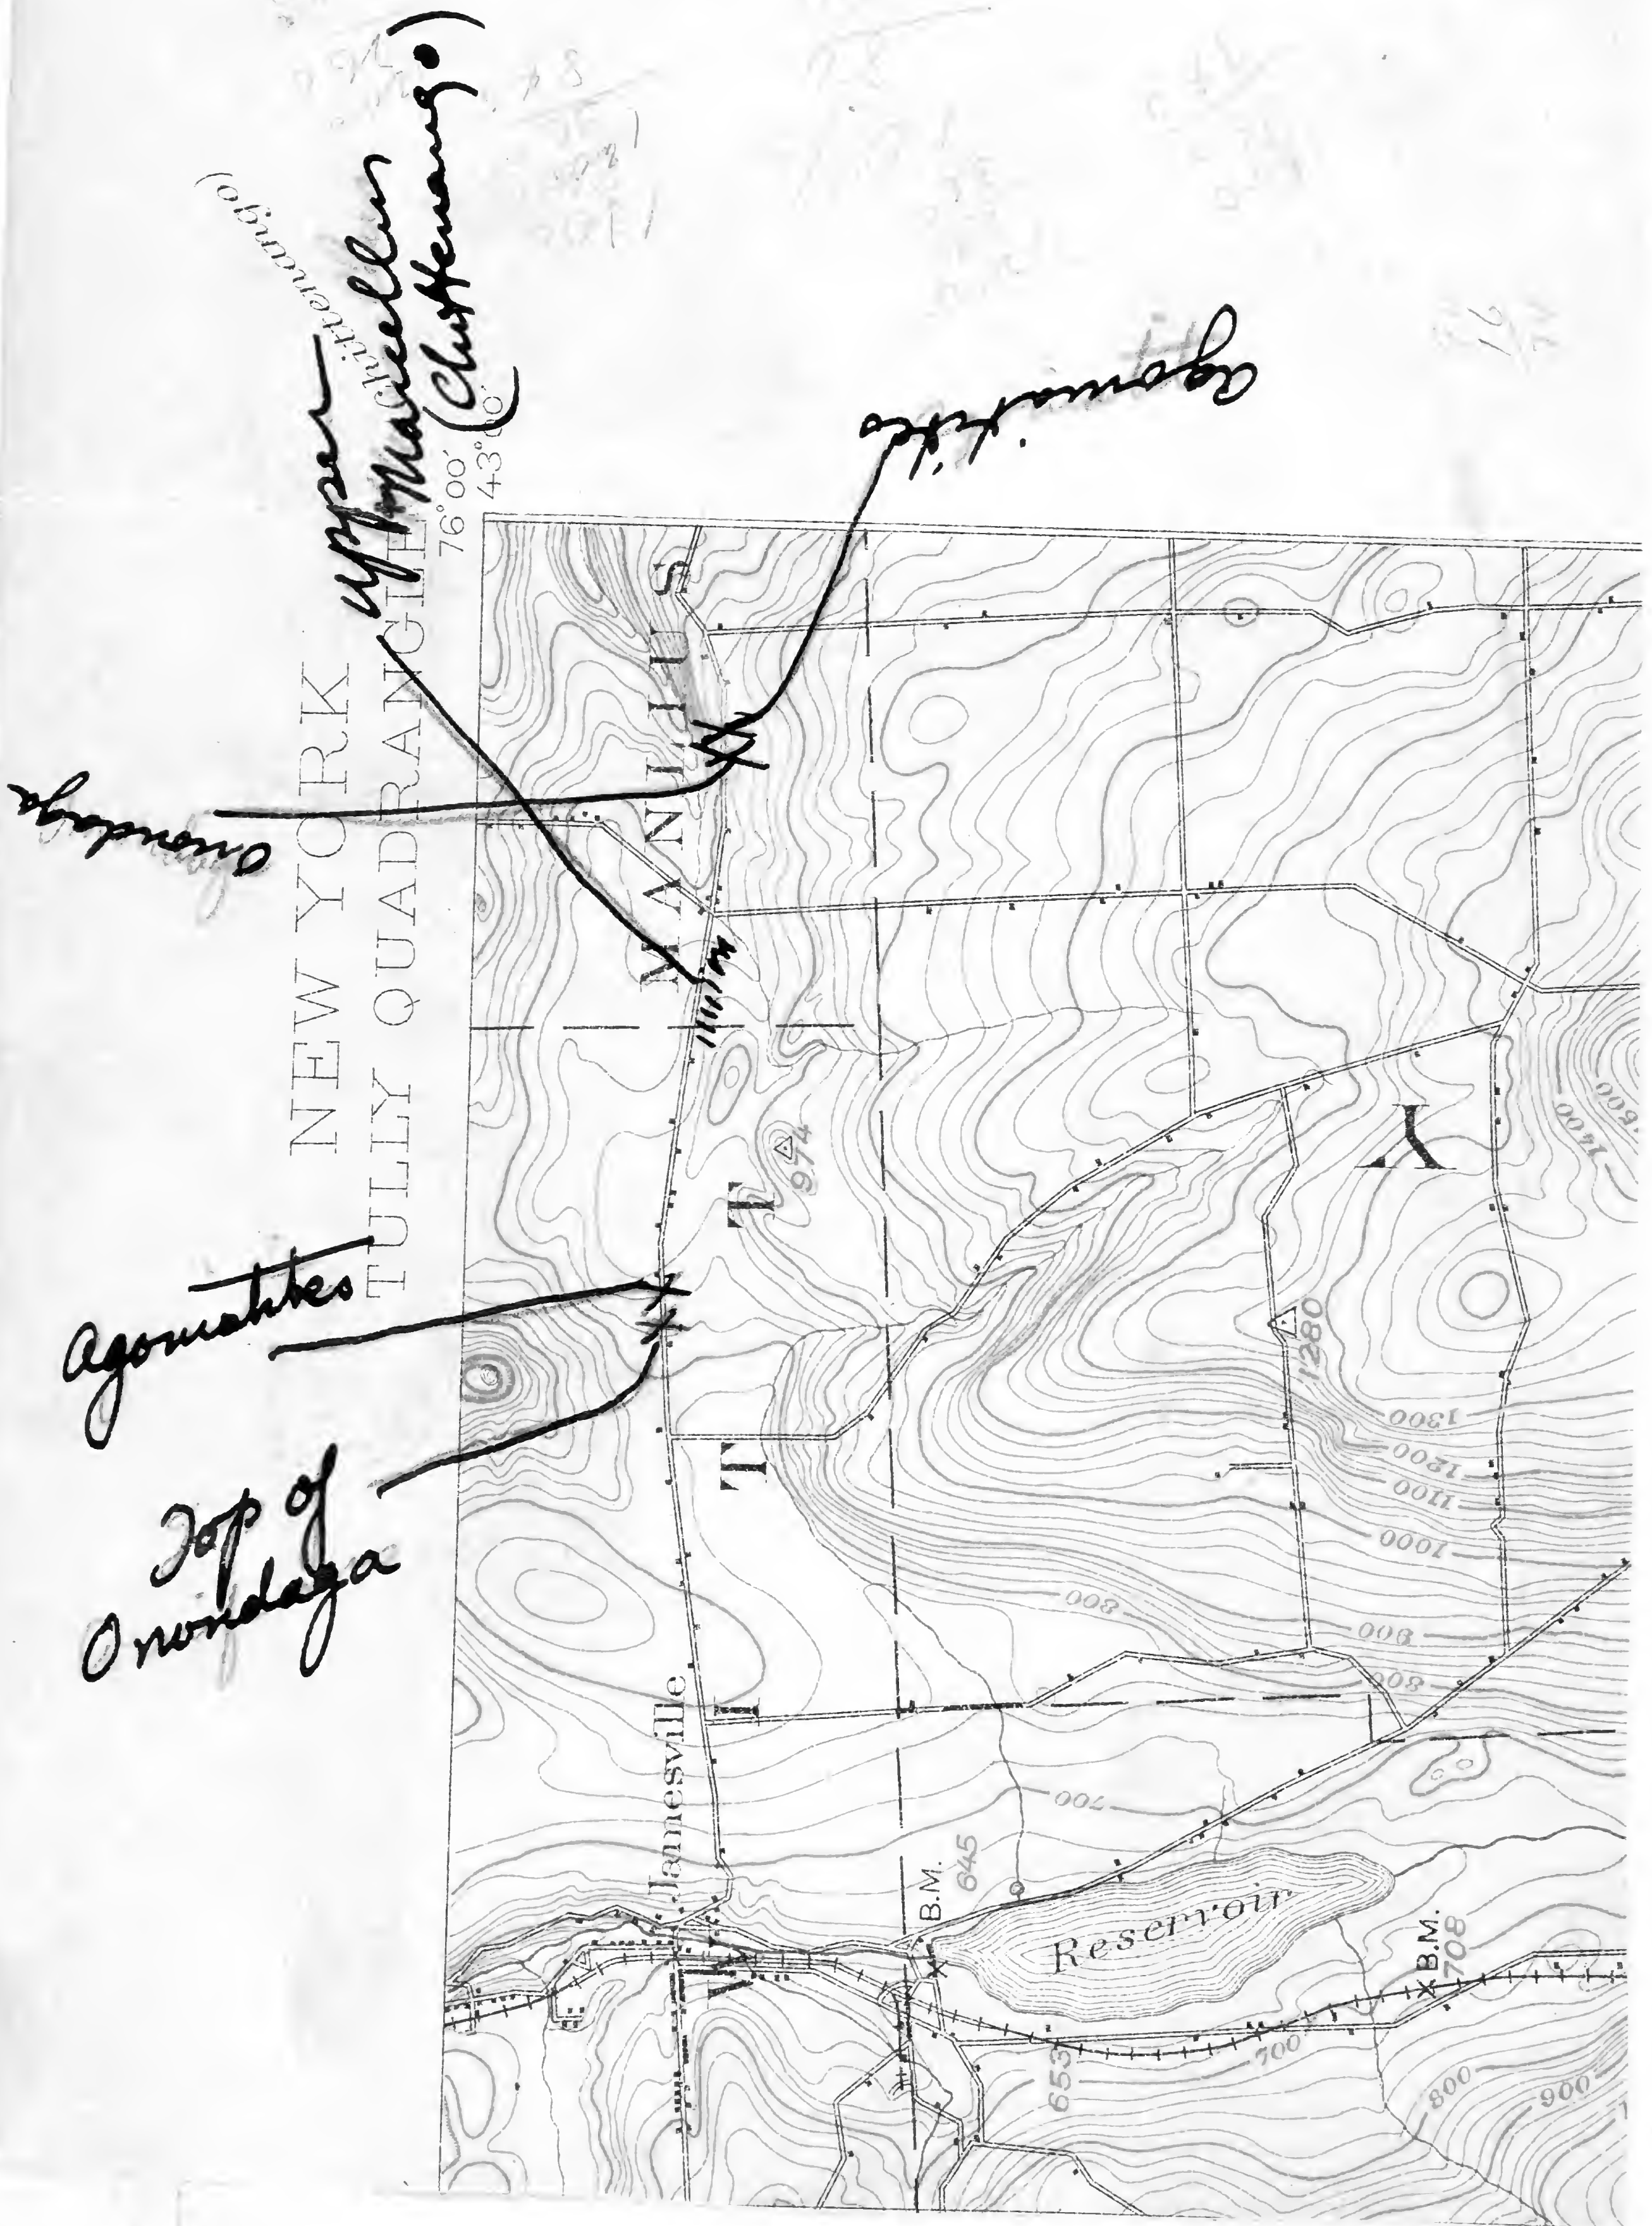

Along the road about 2 miles East of Jamesville the Agoniatites was seen. It is here about 40" thick in 2 layers defined by weathering color. The lower layer is about 14" thick and is a limestone of very even, smooth texture with ^{sub}vertical fracture. On the surface it weathers to a light ashen grey. The topmost layer is 26" thick and is much darker, with a rather blocky fracture and much scarred by horizontal and irregular cracks. This upper stone has also many orange rust spots in it. I also found most of the fossils in these layers. At the junction of the two layers small crinoid stems and tiny brachiopods were accumulated in places.

Between the Onondaga and the Agoniatites there are 2' 8" of black shale with some black ls. bands much as in Madison Co. This was measured by hand level.

The upper surface is somewhat shaly & contains snails, congregated in places & other small fossils.

East of this exposure, which continues up the hill and forms the flat hill there, Upper Marcelus shales are displayed on the hill about 1/2 mile east of Agoniatites outcrop. The shales here are the same as those on Oneida Crk. They also have the peculiar pitted surface

379a

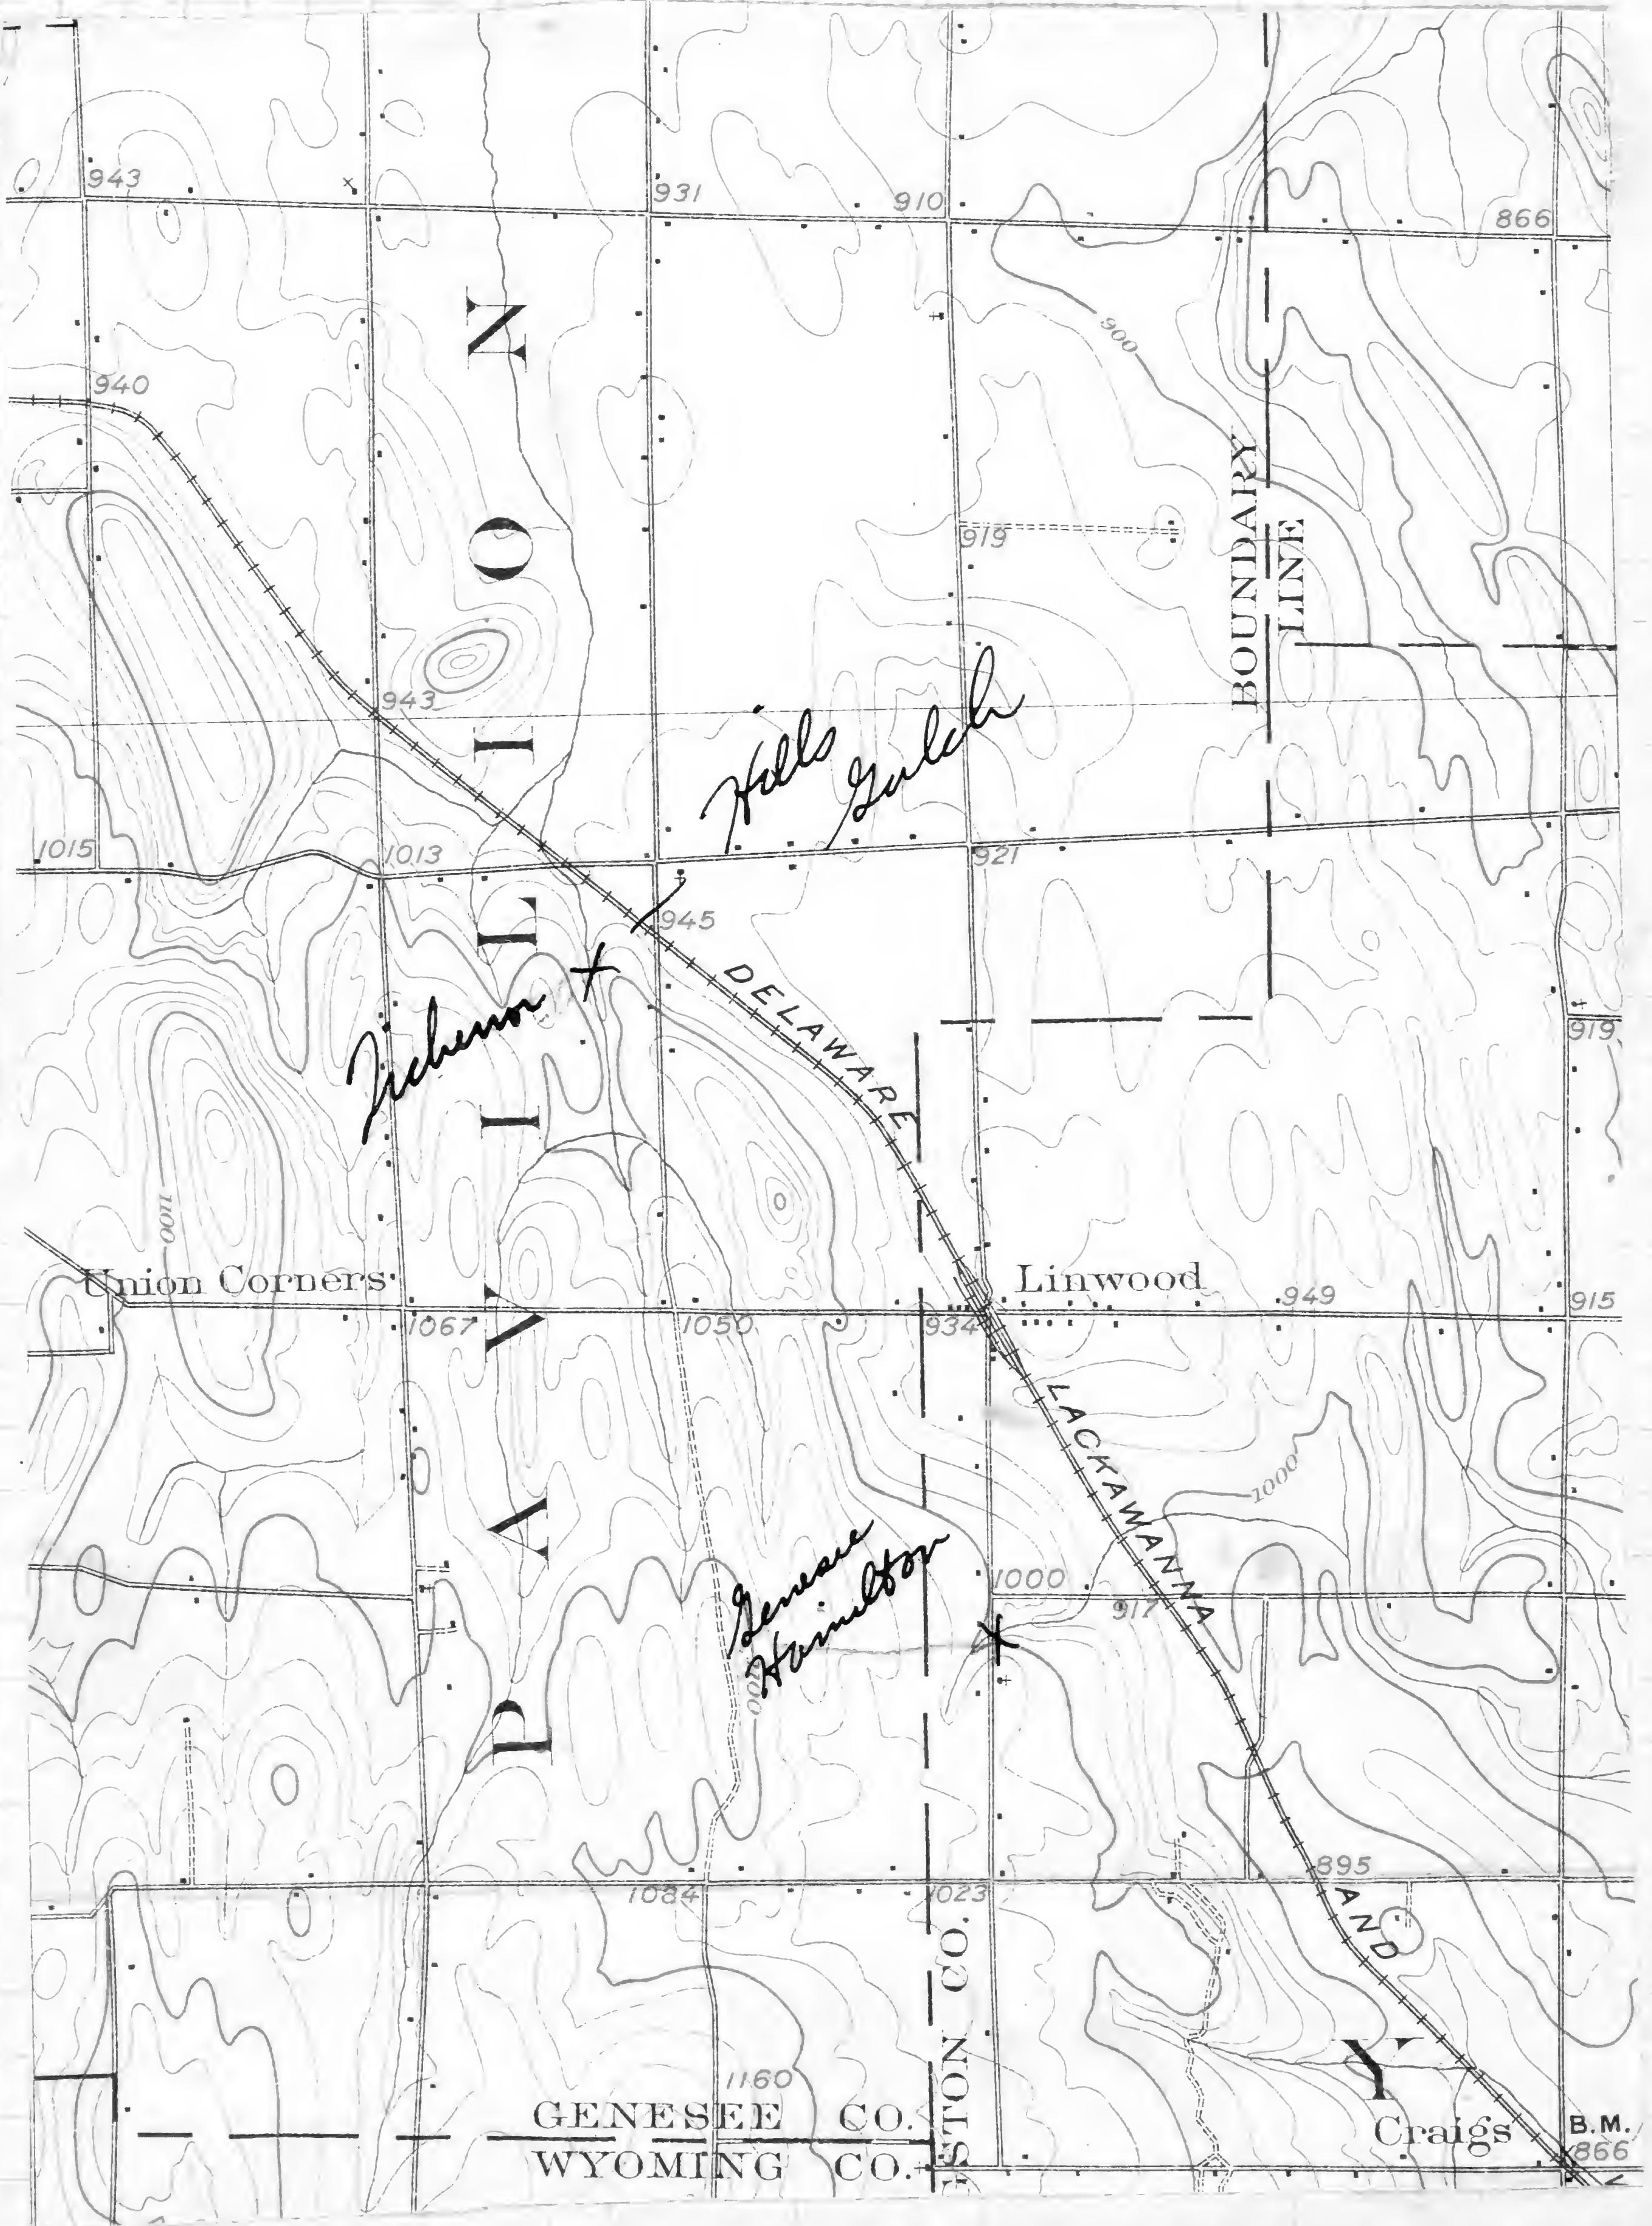

on small flakes. The Agoniatites
 described ~~as~~ ^{are} chunky irregular
 lumps.

Just east of the first road
 intersection east of the first Agoniatite
 outcrop noted and about $3\frac{1}{2}$ miles
 east of Jamesville is another
 that exhibits most of the shale
 and ls. below the Agoniatites + on the
 Onondaga. The Onondaga may
 be seen in a small gully north
 of the road in the hollow between
 the Pompey road and the hill, and
 just west of the yellow house at the
 foot of the hill.

The lower layer of the Agoniatites
 here 2" holds together in contrast to
 the upper layer which as here
 crumbled to bits. The weathering of
 the upper layer brings some of the
 fossils into relief. Cephalopods are
 not as abundant here as in the
 Onondaga Cbs. region.

P. fragilis was noted in the shale
 and ls. below.

1927

Kashong Creek Section.

±60 paces from the highway bridge is to be found a small exposure of dark grey shales in the bed of the creek. These have a conchoidal fracture on the bedding surface and are very slightly calcareous. These have a very sparse fauna -

P. fragilis c.*P. ledum* r.

At 520 paces shales are revealed for about 10-15' vertically. These are dark blue-grey and carry the following fauna for 10' vertically

D. truncata r ✓*Parallobolus* *laevigatus* ✓*P. concentrica* c ✓*M. concentrica* r ✓*A. umbonata* ✓*Lox. hamiltoni* r ✓*S. truncata* ? ✓*Buchiola* sp.*A. spiniferoides* ✓*Orthoceras* sp.*P. stylopoda* ✓*C. bellistriata* c*C. boothii* c*P. rana* r*C. setigenus* ✓*C. lepidus**S. pectinatus* r ✓*Scapellatoia**Camerozoechia* sp.*S. rectum* ✓*S. perplanum* ✓

This bed also contains many concretions.

Between 700-800 paces there is a bank of shale that is easily 60-70' vertical. The shale is very dark, almost black, fissile and much jointed. It is an easy matter to take large blocks and with one blow shatter them into a mass of flake-like chips. The shale in places is friable breaking into paper thin flakes. Between the joint planes and along the bedding occurs small

gypsum crystals have been deposited. Fossils are very rare at least in the lower 10' only which were examined. Here were noted

S. fissurella

P. fragilis

In the stream bed large irregularly rounded oval, or elongate concretions of CaCO_3 protect the shales from the weather and the wear of the water. Pyrite concretions are also present here.

Between 972 and 1030 paces these same shales are exposed in a steep bank. Here additional fossils were seen:-

S. truncata

I. submarginata

Orthis sp.

R. retrostria

E. regulata ?

Pterinopecten sp.

M. triquetra

At 1200-1275 paces is another exposure of these very dark fissile shales. Their appearance is like the Skaneateles shales. At this exposure the fossils noted are

A. umbonata

Buchiola

B. ledus

I. submarginata

At 1030 paces in some spherical concretions there were many *Loxonemas*.

The fauna in the bed ^{4, 5, up} of the stream from 1400-1450 paces follows:-

S. pennatus c

Pal. fecunda

P. stylopoda v r

M. corbuliformis

C. boothi c

Ostracoda

Spirifer sp. ?

Pal. concentrica c

O. parvula

C. bellistriata

S. rectum

Par. hamiltoni

C. scitulus

A. umbonata c

P. discordum

P. rana v

M. liata

Orthis sp.

This fauna and the rocks are the same as those seen at 520 paces. This is either a recurrence of this fauna or a fold that duplicates the strata. The very closely spaced jointing in the rocks so far up the creek suggests the latter

[Faint, illegible handwriting throughout the page, likely bleed-through from the reverse side.]

These dark fissile rocks are exposed above this *Pleurodictyum* bed clear up to 1900 paces, where *P. rana* was fairly abundant in the rocks just above stream-level. At 1900 paces a vertical cliff of 80 or 90' shows a long section of rock. At 1750 paces some of these quite ^{dark} shales were found weathered and here they are olive colored. I fully believe that a small fold has duplicated the *Pleurodictyum* bed.

At 2075 paces is the bottom of the falls. Here the hand level was used. Fossils of the 1st 5' 5" of shale - the bottom 2 1/2 - 3' had practically no fossils.

✓ *P. pavilionensis*

✓ *S. macronotus*

About 350 paces upstream the hard calcareous rocks have passed under the stream. Of these above the Tschener there must have been about 15'. The beds that disappeared at about 350 paces were very fossiliferous but the fossils were difficult to procure. From this elevation on shale rocks prevail. These are dark blue-grey like the Earlville rocks and give a vigorous effervescence with acid. They offer a faint guttiness to the teeth.

At 397 paces, 5' above stream level were found *C. boethe*, & *Orthoceras* with *R. stolbnifera*. *Tegomurus*

At 470 paces *P. tenuis*, 496 in debris, *Platthoria cylindrica*

At 583 paces a falls occurs over these blocky coarse shales. Fossils are very few here. Only a

Pterinopecten was found, but a
J. carinatus was noted in the debris.
 a large *Grammysia*

At the top of the 3rd falls is hard
 ls. band a little more than a foot
 thick and contains *S. pennatus* and
C. scitulus. The falls is 27' high + 3'
 to the top of the ls. 57 paces above the
 falls or 640 paces from top of Fichon
 the shales are soft and blue grey,
 breaking into small flakes. The rock
 contains *J. carinatus* and small
 concretions containing also *J. carinatus*
 not unlike those seen above the
 Menteth ls.

Here are

S. granulosa

C. coronatus

J. carinatus cc.

At 648 paces in the stream bed there
 is a band of ls. containing the following
 species:-

S. granulosa cc

Camartoechia sp.

S. lineiguttata

Cent. impressa

P. rana

C. bellistriata

A. spiniferoides

R. vanuxemi c

E. lincklaeni

It is a hard shaly ls. and is about
 3' above the hard ls. at the top of the ^{Menteth}
 falls. On this are about 10' of shale
 and then there is another hard
 band of ls. In the intervening rocks
 between these 2 ls. are found

At 731 paces there is a cascade in the stream about 5' high. Thus in 83 paces the stone has dropped about 5' but it rises again, being about 3' above stream level at 814 paces above the Tichenor.

Just below the calcareous band causing the cascade fossils are numerous and here were found

S. perplana
Modiomorpha sp.
Cyrtodictya sp.
H. carinatus
C. coronatus
H. dekaiei

A. spiriferoides
S. pennatus
S. concava
C. vicinus
R. vanuxemi

This 10' of shale contains also many concretions.

Bridge is at 814 paces upstream from Tichenor

August 8.

Bellona

Rain all morning; took trip into Penn
Yam to ship package and notes. In
afternoon worked under dam. Here
about 15' of rocks are displayed below
the Tully ls. which is well exhibited.

In the floor of the stream are
slightly calcareous shales which
crumble easily. There are local lime
concentrations in the form of concretions
and local layers of fossils. *A. reticularis*
is specially abundant here, along with
S. rectum. Fauna in ^{183'} 13' feet below Tully.

Between 13' + 15' below the Tully
A. reticularis, the corals and byozoa
 come in. Also in this interval the
 shales become less fissile. It may
 however be because they are nearer
 the stream & less subjected to the sun.
 There are here 18' 3" of shale exposed
 below the Tully.

Tully

Mounds in Moscow. Under dam
 appears to dip to south but probably
 reverses its dip and appears upstream
 again dipping north, thus making
 here a shallow trough. It consists
 of 5 layers, the lower one is 2' 2" thick.
 The next is 5" thick, the next is 2 1/2'
 the next 1' 9", and the last which is
 shaly & bears corals is 3-4". This
 makes the total thickness 7' 2". By
 hand level I made it 7' 10".

The lower layer has crinoid stems
 in it. The upper 2 layers bear corals
 and at the ^{convergence} contact on the north
 side of the dam these are very
 abundant in a shaly ls.

The rock when weathered has a
 tendency to split into large or small
 angular, irregular, blocky fragments
 so that with a single blow

a large boulder can be shattered to bits.

A short distance south up the hill and then east along the first dirt (private) road to the top of the hill and $\frac{3}{4}$ of a mile along it is a quarry in the gully. The stone is so fragmentary that the ordinary quarrying methods are not necessary and after blasting it can be shovelled up. (not actually seen in operation but judged from apparatus & condition of rock).

Aside from corals I saw few fossils in the Gully. *P. rana*.

A little east of the dam in the woods the Gully appears to have ~~only~~ 5 layers. The lowest is 23", the next 5", the middle one is 31", the next 22", and the last 2" = 7' 1".

The Henessee on the Gully was not calcareous.

In places the surface is marked by furrows or matted masses of stem-like forms.

The stone is the usual blue gray on a fracture surface.

Aug 9.

Fauna of hard ls band: at 731
paces above the Lichenor: -

S. pennatus cc *P. rana*

C. mucronatus c

Wood

C. scitulus

C. coronatus

This 4" of stone is very hard and is a
grey ls. like that at the falls at 583
paces

Below this band in the shales with
Gymnysia, etc. were noted *S. pennatus*,
C. vicinus and *C. incisurata*, *A. erectum*?

In the shaley ls. just below the harder
4" layer are: -

✓ *S. concava* c.

S. rectum

✓ *S. perplana* c

✓ *S. carinatus* c

✓ *C. coronatus* c

✓ *S. grandis* cc

Crinoida

C. boothi

T. exigua

✓ *A. princeps*?

~~*Pal. constructa*~~

✓ *Pal. constructa*

This zone with *S. concava* is about 1 foot thick and overlies the concretionary bed of about 10' that carries *J. carinatus* and *Pleurodictyum*. This foot is divided into two parts, the lower & very fossiliferous part is a shaly ls., the upper is characterized by abundance of *S. pennatus* but few other forms and is only 4" thick. The upper 4" is the most resistant and well displays the gentle undulations of the rock.

Ls. at 583 paces restudied:-

~~*C. coronatus*~~

Tarmonius c.

P. rana (huge)

J. carinatus

S. pennatus

} Found in the 1' below the ls.

This ls is one foot thick and contains

S. pennatus

J. carinatus

P. rana huge

C. setigera

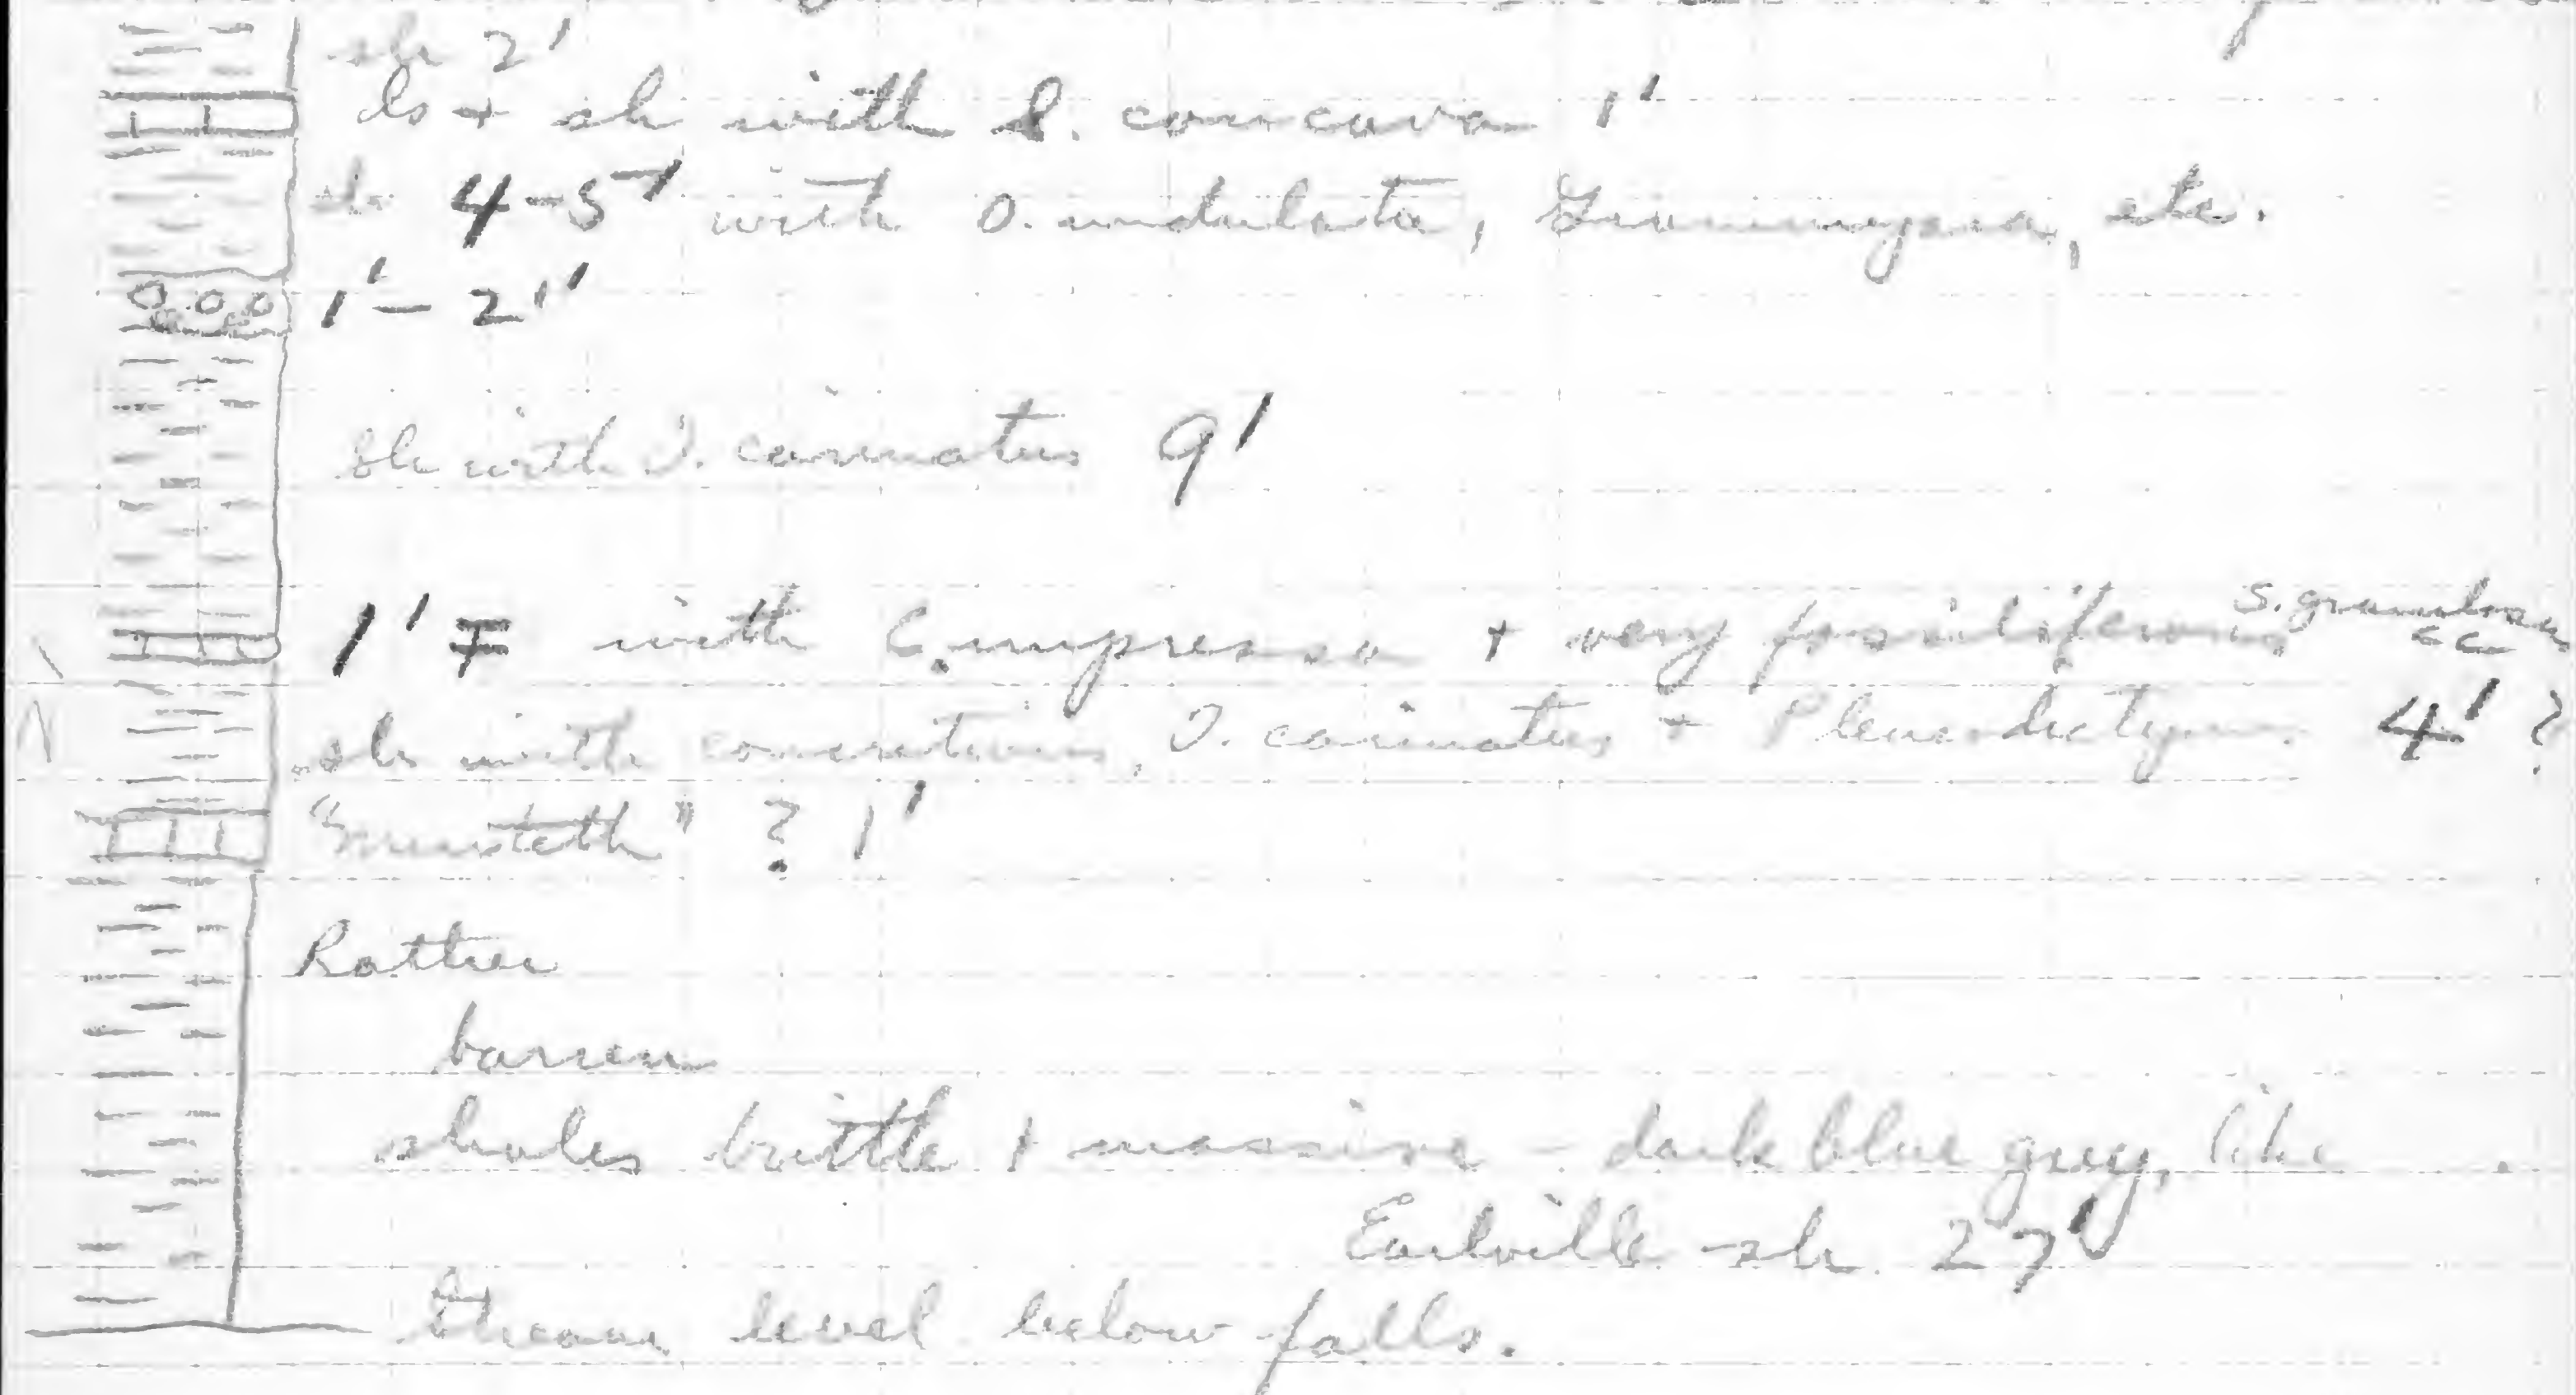

S. granulosa

C. coronatus

It is a very hard even grey ls., 1' thick and may be the Menteth. It is overlain by 10' shales carrying *J. carinatus*, concretions and *Pleurodictyum*, as is the Menteth at Menteth ridge. The ls is nodular in local patches, contains some shale and also *Tarmonius*. It dips rather strongly, I should judge about a degree or more into the stream and this is its only appearance. It is exposed from the ledge of the falls to about 30 yds upstream. On a weathered face irregular (flint-like) masses stand out, also some of the fossils, and these two phenomena were noted in the

Menteth.

50 paces upstream from Menteth? comes a calcareous band a few inches (5) thick containing *C. impressa* and 30 paces above this comes the band with *S. concava*. The section is about as follows:

The 2' of shale on the *S. concava* band carry:

| | |
|---|--------------------------------|
| <i>C. mucronatus</i> c | <i>C. boothi</i> |

This shale is coarse and very gritty to the teeth. It contains a few concretions, one of which contained a great deal of sphaerulite.

At 731 paces the 4" ls on the S. concave band forms a cascade, at 583 paces it is about 21 or more feet above the "Menteth". At 814 paces the concretionary bed below it is at stream level & the ls is about 4' above stream. This is just under the bridge at 814 paces. At 844 paces it is 8' above the stream. At 948 paces it is still 8' up but beginning to drop. At 987 paces the concretionary layer is again in the stream. At 1046 paces the band is 1 1/2' above stream level. At 1130 it is 2' above stream level. At 1179 and for 47 paces the concretion band is exposed in the bed of the creek. At 1351 the concretionary band is 5' above stream.

The coarse shales here below the concretionary bed yielded:-

| <i>G. arcuata</i> | <i>J. carinatus</i> cc. |
| <i>Pal. concentrica</i> | <i>S. marci</i> ? |
| <i>J. submarginata</i> | <i>P. lanceolata</i> |
| <i>S. salenoides</i> | <i>Lebiodus</i> sp. |
| <i>P. discoides</i> | <i>N. oblongatus</i> |
| <i>C. coronatus</i> | <i>B. lada</i> |
| <i>Lingula</i> sp. | <i>Grammysia</i> sp. |

At 1410 the S. concave band is 10' above stream level. 1570 paces it is 8' above stream. 1650 paces the concretionary band goes below stream level. (1603) paces the S. concave band is in the stream bed & forms a 2' cascade. At 1788 paces the 3' of sandy shales on the S. concave band forms a long flat in the stream bottom. No sandy shale is exposed for 4 1/2 above the S. concave band.

It has

1860-1919 - liatus. At 1919 paces the following were found.

A. umbonata c.c.

Phol. hamiltoniae

Pal. secunda

C. bellistriata

There are almost continuous exposures of this rock to 2185 paces.

At 2300 a long exposure in places very high begins. Here along the creek + 5' up the following are found: -

M. pygmaea

C. scitulus

Pholidops hum.

P. rana c.c.

C. boothi

N. liata

A. praecumbosa?

C. setigera

Pal. constricta

A. umbonata c.c.

C. bellistriata

Arenulopecten sp.

S. pennatus

M. pygmaea

N. corbuliformis

The shales here are very dark grey. This rock is exposed for 150 paces.

Except for a small exposure in the stream no rock is exposed from 2450 paces to 2560 paces. Here at 2560 *A. umbonata* is still common. This exposure is only 12 paces long but is 120' vertical.

2272 - 3050 liatus. At 3091 paces the following species were seen: -

A. umbonata

P. carinatus (small)

P. rana

Pholidops hamiltoniae

C. mucronatus

A. praecumbosa?

N. corbuliformis

C. bellistriata

S. andanulus

N. oblongatus

A. spiniferoides

S. imentum

S. granulatus

partly
20-70

At stream level the shale is hard and in places is a ls. containing *S. rectum*. Above the stream the rock is soft + dark.

In the ls. (thin band at stream level)

at 3650 paces about 30-35' of Moscow are displayed under the Tully. It is a light grey rock containing many concretions and lenses of ls. which contain the fossils. From here to about 12' below the Tully *A. reticularis* & *Spinifers* with *S. rectum* & *Endoplyllum* prevail.

At 3735 paces - *S. concava*, & *I. limbata* can be added to the list of species.
I. carinatus, *R. vanuxemi*, *M. concentrica*
 3860 paces to bottom of dam.

Tully makes another falls beyond and behind the village.

August 9.

Just outside of Geneva along the lake Road on the east side of the lake and under the Lehigh Valley bridge is an exposure of Cardiff shales which in the lower 3' are blue black in color on the surface when fresh but on a fracture section are a very dark grey. The shales give a grey streak. Fossils are rare but *C. setigerus*, *B. lida*, *Leiorhynchus* sp., *P. fragilis* were noted in the first 5'. Orthooids sp. There are a little more than 20' of shale exhibited. On the surface it is light green to a very light green and where leached an olive color, even in section.

Retrospect on Keshong Creek, Wisconsin

Above the Tichenor comes a very fossiliferous band for about a foot, then several feet of hard, sandy(?) calcareous shales, followed by calcareous and very fossiliferous rock, which is succeeded for a long interval by rather unfossiliferous shales. Prolonged collecting however would probably bring to light from these a good Paleozoic fauna. On these shales at the 3rd falls is a ls like the Menteth & on this shales with *J. corinatus*, capped by a band of calcareous stone bearing *S. concava*. Upon this is a long series of shales containing a fauna characterized by *Atrypa reticularis* & *Strophomena*. This is interrupted about 40' (?) from the top by a zone with *L. laura* and *A. praeambona*. Below the *Atrypa* zone is a long Ambocoelia zone. Just under the Tully were about 12' shale with *L. laura* & *S. tullus*.

July 13.

White Creek - short collecting and recording
 worked in stream bed and for about 20-25-30
 yds. to limestone shales, nothing to record
 fragments on falling to a clay. But when between
 the strata there is a bed of sand. Also the
 stream bed and throughout the section are
 courses of calcareous and pyrite concretions, or
 a combination of both. There are small
 nodules and often globular, in shape,
 and always irregular. They are
 well preserved fossils, sometimes pyritized
 fossils.

In the stream bed and for about 20-30
 yds. above the following fossils are common:

Aspidomera

is planum

is planum

Other fossils are *Pholidops*, *Phragmites* and
Cyrtolites, *Platystrophia*.

Also the upper part 20-30 yds. of the
 shale is *Aspidomera*, *is planum*, *is planum*, *is planum*
 (eye, indurated) and a couple of *Aspidomera*
is planum were also noted.

The top of the *Aspidomera* is a thin
 shales and is a thin brownish-grey
 ls., granular with many small
 fragments of *Aspidomera* fossils. It is
 not a shales but a pyritized
 cylindrical *Aspidomera* is a limestone
 on the top. The upper shales are
 red for a thin *Aspidomera* fossils into
 a shales. *Aspidomera* noted -

D. sculptilis

Above the Tichenor are grey shales,
 breaking & weathering into large fragments.
 Near their base are many corals and
 at the base *A. decussata* is very
 abundant.

Note: There are masses of ^{ls.} ~~ls.~~ in some
 of the Tichenor blocks that appear shaly
 and like some of the calcareous concretions
 with bluffs, in texture. These patches or
 patches are very fossiliferous at times.

July 14.

Cardiff Shale — Exposed in the low cliffs along the shore directly behind "Bob" Smith's Bay View hotel. Directly behind the hotel the shales are about 8' vertical and are ~~dark~~ grey on the dry weathered surface. In cross-section they are dark grey with a brownish cast (olive). A cursory examination showed only *Styliolina* but in great abundance in the layers about 3' above lowest rock exposed (which is about 2-3' above H & O level). The streak of the shale is brownish grey. In the lower layers when they were fractured they had a distinct bituminous odor, much like oil shale.

A loose calcareous slab there had many *Styliola* and also a *Spirifer* perforated in it.

140 paces south of hotel section is 13' 10" thick. Lower and upper layers have *Styliola* in abundance. It seems to range through the shales exposed here from 10' - 13' 10" other fossils were noted but none are abundant.

H. trigona ✓

✓ *Orthoceras*? sp.

H. oblongata ✓

✓ *Snail* (*Burroughsia* beds?)

C. setigenus ✓

Some of the layers

are quite calcareous notably in the bottom along the H & O level, forming a bench along the beach. This is not however a significant layer. It yields bituminous in section. The shale at 13' has a brownish cross-section somewhat like that on Ananda Lake.

2140 paces south of Smith's (Bay View Hotel) exposures of shale rock are again met with and are about $17\frac{1}{2}'$ vertically. These are exposed behind Louis' Lake Shore Restaurant. The lower 9' are shale giving a bituminous odor when fractured and bruised.

Section at Athol Springs about 100 yds. s. of Louis' Restaurant. The Cardiff below this — 5' 5" shaly ls. is somewhat carbonaceous.

Section a short distance south — between Athol Spr. & Hanaburg Park

The 2' calcareous band is succeeded by 10' (here) of very soft shale that crumbles to fragments even smaller than the Cardiff below. This shale like that below effervesces with acid.

Here 3' calcareous sh bed at base of shaly bedwards $11\frac{1}{2}'$ in 1375' which amounts to about 44' per mile as one component of the dip.

Just north of Hamburg Park

Gen. sh. -

On top of the 2' shaly ls., which is hard and forms a rising bench all along the shore are soft gray shales that can be crumbled readily to a clay. These fall naturally into thin flakes. The formation as exposed here is not very fossiliferous. In the 2' ls. sh. were noted *C. retigera* and *L. larva*. In the soft shales *P. fragilis* and these shales are in strong contrast to the Ludlowville shales above, with their numerous fossils and many courses of concretions. Concretions in this bed at Bethel Springs are confined to about 15' above the 2' band of calcareous sh. They are calcareous and spherical.

A number of concretions were opened but none contained fossils. Some beautiful specimens of *S. pennatus* were found in the tubers along the cliffs. They were not so rounded by waves and their freshness strongly suggested their origin from the Shale above. These shales are calcareous, effervescing on a fresh fracture with acid.

S. pinnatus, *Palaeonilo*
terminata?, *Stenopecten*

Tichenor 1 1/2'

Rhipidomella vancouverensis?
C. levis

A set of joints here is N69W vertical and
irregularly spaced from 1 1/2' - 5' 7" +
an intersecting set at S65W - vert. The
total thickness of the Moscow is measured
here as 26' 9" or 27'.

The shales from the top of the coral
bed up to 12' 10" are quite barren of fossils
except for *P. rana*. At 12' 10" there is a 2"
band of concretions and this is a foot
thick of sh (exact amt? not more than 6")
There then succeeds a band of calcareous
shale (ls) forming a cascade in
the brook. This is about 6" or a foot in
thickness, the exact amt. cannot be
ascertained. This bed. *P. rana*, *Oronites*,
Spirifer subumbonatus?

Between the upper bed of concretions
and the Remondish ls. fossils are
fairly abundant. The concretions do not
contain many fossils altho one had a
specimen of *M. subumbonatus*? Fossils
occurring in the shales here are:-

M. subumbonatus?

C. setigerus

L. laura?

P. rana

O. Rudolphi

C. mucronatus

Many of the shales contain
large pointed concretions of irregular
shapes.

10 1/2' of shales follow - Then
comes the Jackson or is 10' thick
2' below Dickinson a spirogonite
and a actinularia and a small
The Jacksonville shales have exposed
here are not calcareous, except
for the concretions.

Moscow Division

In the Jackson are 10 1/2' of shale
with many Cyrtophylloids and
on these shales a 2' band of shale
with a actinularia and spirogonite
followed by shale on the
bottom of which just above the

upper 2' band of ls. and small corals

like those found above they
are corals in zone in layers.

The shales here are slightly
calcareous. At the top of the Mos

at the 11th step (22') the shales
have M. subumbona? and

also C. centularia. There are at least
5' more of Moscow actually

uncovered. The Genesee shales
exposed in here is about 3'

2' more, making a total of about

10 1/2' shales with Cyrtophylloids 27'-30' for
the Jackson 10'

The M. subumbona may be a. praeumbona
as the case in the layers they are
found just below the Genesee shales.
If correct for M. subumbona + 2' below
for a. praeumbona.

Only Ludlowella - not common & small

18-mile Creek

Section west of highway bridge

Bed of creek is a limestone ledge
that forms a shelf in the water. This
bed contains:

| | |
|------------------------|----------------------|
| <i>P. sinensis</i> ✓ | <i>D. sinensis</i> ✓ |
| <i>P. sinensis</i> ✓ | <i>Coralis</i> ✓ |
| <i>P. sinensis</i> ✓ | <i>M. sinensis</i> ✓ |
| <i>P. constricta</i> ✓ | <i>Platys</i> ✓ |
| <i>P. sinensis</i> ✓ | <i>P. sinensis</i> ✓ |
| <i>P. sinensis</i> ✓ | <i>C. sinensis</i> ✓ |

According to Graham this is one of the
Palaetina beds (lower) at least 6' thick on the
Creek.

Next above this is a shale
bed 11" thick containing: - *P. sinensis*, *D.*
pennatus, *C. I. carinatus*, *A. spiniferoides*,
A. umbonata, *Palaetina* sp., *C. scitulus*

This is followed by 4" of hard calcareous
stone which is somewhat gritty. This
stone forms a ledge in the stream bed
along the cliff. Here are found *D. fissimella*,
C. Boothi, *C. I. sinensis*, *Aulopora*, *P. pennatus*.
Fossils are not as common in this
bed as in those below. *Spirifer*, *B. beds*.

July 18.

Lawrence N.Y. — Stafford Is. Cayuga Co.

Under the ^{Lake} Avenue bridge a 10" layer of very hard ls. which is very fine grained and grey. Fossils here are Ambocoelia, C. mucronatus, L. divistare? Upstream and between the two bridges just below the dams, are 2 layers of ls., the lower one downstream 90" thick, the upper one at the dam is of 2 layers amounting to 1'. Thus about 22" of ls. are exposed between the two bridges. On the uppermost bed under the street - low bridge there is a 2" layer of calcareous shale with crinoid stem segments and C. mucronatus.

Stafford Is.

275 paces below the Court Street bridge ^{at the foot of Pennsylvania} were found small outcrops of Marcellus shale below the Stafford Is. The thickness of the Marcellus exposed here is about 1' 2". The stone is not the typical black fissile shale with paper thin bedding but is dark grey some of it with thin brownish layers. It has a conchoidal fracture and a granular structure. 200 paces below the Court Street bridge the shale is black with a conchoidal fracture and is calcareous.

The upper shale below the Stafford is gritty and more compact and is very calcareous. It is a very calcareous shale. The stone here

is also quite fossiliferous. The species observed are:

Lunulicardium cuneatum

L. limitaris

Orthis (probably *Orthis subulatum*)

P. fragilis

N. triquetra

P. lincklaeni

C. mucronatus

A. umbonata?

One of the layers is a limestone 1" thick. 150 paces further below the lowest layer of the Stafford noted which is a ^{1 1/2' thick} ~~massive~~ ^{soft} brownish grey shale. The total thickness of marcellus exposed must be 3-4'.

The lowest bed of the Stafford is 18" thick and is a hard grey ls. crowded with small *Ambocoelids*. Also present here was *C. scutellus*. This first bed is 18" thick. Then follows a bed 19" thick in the lowest portion of which occurs corals in the shale parting. These next 6" are compact & hard then the rest is composed of ls that appears hard but when struck falls to flat plates. On the pocket (solution) surfaces of these blocks the partings between these plates appear like contours. In places the rock has a decided concretionary structure. In the ls. which breaks into plates well preserved specimens of *C. scutellus* are very abundant.

The uppermost bed exposed is just below a small ledge about 50 yds from street bridge. It is hard and compact and has many fossils.

It is a grey ls, with a flinty fracture. It was not possible to land level this ravine with the result that the thickness could not be measured. Further gives it as 9' 5" which seems high. I would make the layers exposed here 5' 6" to 6' in thickness. Probably all of the rock is not now exposed. Thin layers of shale are found between the parts of the major beds.

Cardiff sh.

At the junction of Little Buffalo and Cayuga Creeks there is shale in the creek bed but above this a stratum of rather hard ls. forming a ledge. This layer is probably the same as that which divides the Cardiff from the Glencairies at the Erie Lake shore. The shale here is calcareous. The shale in section is a dark grey and is about 6" thick. The ls. is about 15" thick. Fossils observed in the ls are:-

P. rana

Styliolina ✓

A. umbonata ? ✓

L. laura ? ✓

S. pennatus ✓

S. subulatum ?

P. leisteri ? ✓

C. boothi

A set of joints opened about 5' here reads N 72 E and an intersecting set, less regular reads N 22 W. The shales above the ls are darker in color than those below. Correct

When the ls has been exposed to the weather it crumbles to small chips and thus leaves a very irregular surface. About 3 ft of shale is exposed above the ls in the creek upstream from the highway bridge. It is brownish gray in color and when struck with the hammer it leaves a brownish streak on paper. It is quite sulcaceous with acid. Large rectangular blocks in the stream bed brought from above are of a siltular kind, showing the nature of the rock above.

The Shafford appears to be about 33" thick with the Hurley lower limestone and the upper heavy bed. The latter varies considerably in thickness.

The shale above the Shafford has lacks the fine color of the Hurley.

July 26.

Lithon on Little Beards Creek - Moscow

Section

950 paces from the intersection of the north branch of Beards Creek with Little Beards Creek Moscow is exposed as grey calcareous shales that crumble easily into small fragments. On the opposite side of the river at the same place (950 paces) the shales have a concretionary structure and fall to small pieces or fragments when exposed to the sun.

In this one foot of shale exposed here fossils do not occur abundantly. *C. boethi* and *C. biculata* were the only ones seen.

In the shale above this one foot the following fossils were found. Just under the 6" calcareous shale band were found:

Pholidops hamiltoni, *C. acuta*, *Protocrinus* sp. These shales when weathered have a greenish or olive cast.

With it + *T. d. 202* / *T. concolor*, *A. reticularis*, small corals,

small corals,

also the 6" calcareous band are *Protocrinus* sp., *C. acutus*, small corals (*Strophomena*)
